NEW YORK, SATURDAY, JANUARY 1st, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## RETROSPECT OF THE YEAR 1909

### Exploration

The year 1909 will forever be famous in the annals of scientific accomplishment as having witnessed the successful culmination of the age-long quest for the North Pole, and the achievement of Commander Robert E. Peary of the United States navy in finally reaching this theoretical point at the dome of the world after twenty-three years of practically uninterrupted endeavor will stand as the most difficult feat of geographical exploration in the history of the world. It was eminently fitting that Peary should be the first to reach the North Pole, for among all the Arctic explorers he was easily the first in practical knowledge and experience. When he announced to the world on September 5th that on April 6th, 1909, he had reached the coveted goal, his word was accepted without question. Subsequently his data was passed upon favorably by the National Geographic Society of America, which later presented him with its medal, and the verdict of this tribunal has been tacitly indorsed by the various learned societies throughout the world.

In our issue of September 11th, commenting upon the freely expressed doubts of Dr. Cook's claim that he also, and a year earlier, had reached the North Pole, we wrote: "The man who can look Death full in the face throughout all the cruel sufferings of a two years' search for the secret of the frozen North is built upon lines too noble to admit of the slightest subterfuge or misrepresentation." It was evidently with the same conviction that the Danish authorities and the Danish people at large accepted Dr. Cook's stupendous claim in a spirit of loyal belief which appears never to have wavered until the fiasco of the receipt of his so-called data by a committee of the University of Copenhagen. These gentlemen very quickly reported that Cook's statement was the same as that printed in a New York newspaper, that the copy of his notebooks contained no original astronomical observations whatsoever, but only results; that the documents presented were inexcusably lacking in information which would prove that the astronomical observations therein referred to were really made, and that they contained no details regarding the practical work of the expedition and the sledge journey which would enable the committee to determine their reliability.

By this sweeping repudiation of Dr. Cook's claims the University of Copenhagen has drawn the final curtain upon one of the most spectacular dramas of audacious imposture in the history of geographical research.

Second only in importance to Peary's achievement in reaching the North Pole was Lieut. Shackleton's wonderful journey in the Antarctic, when he succeeded in reaching latitude 88 degrees 23 minutes south, and arrived within 111 miles of the South Pole. Shackleton passed the very point reached by Scott in 1903, pushed on for 325 miles, and was defeated in his quest by hunger, fatigue, sickness, and the loss of his dogs and ponies. He discovered eight new and distinct mountain ranges and over one hundred mountains, and ascended Mount Erebus, the most southerly volcano. The south magnetic pole was reached at 72 degrees 25 minutes.

### Civil Engineering

With the single exception of the harbor at Dover the past year has not been notable for the completion of any engineering works of the first magnitude. This stupendous work, by which a harbor capable of floating a whole fleet of the largest warships has been wrested from one of the stormiest seas in the world, consists of an aggregate length of over two miles of breakwater, much of which is nearly 100 feet in height from its foundation to its crest. It incloses about one square mile of area, and cost some twenty million dollars.

In spite of many predictions of failure, the United States government, through its army engineers, is building the Panama Canal with a rapidity which augurs well for its opening by January 1st, 1915. Over one-half of the excavation at the Culebra cut has been done, and if we include the work done by the French, the cut may be considered as two-thirds completed. On the Atlantic side between three and four miles of the entrance channel have been completed, and on the Pacific side the channel is open to full depth for about five miles. At Gatun the lock excavation is so far done that the laying of the concrete floor and the building of the walls is well under way, and over eighty thousand cubic yards are already in place. The cut for the spillway has been completed, and here also concreting is making good progress. The method of building the Gatun dam by hydraulic depositing is being followed with every promise of securing a perfectly watertight structure. The locks, which will be in pairs, will be 110 feet in width, with a usable length of 1,000 feet. They will be provided with an extra pair of heavy mitering gates to act as collision bulkheads. Plans have been completed for an emergency dam at the head of the locks, which, in the event of a gate being carried away, will be swung across the entrance, and wickets resting on girders extending from the bridge to sills below will be successively lowered until the flow of water is cut off. Throughout the whole length of the canal the method of excavation by steam shovel has been eminently successful, and during the month of March a maximum record of excavation was reached of 3,880,437 cubic yards. The health conditions have shown steady improvement, and the rate of sickness and mortality is now less than in some parts of the United States. The increasing size of ships, both merchant marine and naval, has led the German government to undertake a great enlargement of the Kaiser Wilhelm Canal, which is to be deepened to 36 feet, with provision for a later deepening, if necessary, to 46 feet. The width of the canal is to be doubled, and the locks will be 147 feet broad, 46 feet deep, and 1082 feet long. During the year work has progressed steadily, if somewhat slowly, upon that other great work of canal excavation known as the New York State Barge Canal. While it must be admitted that there can be no comparison on the score of accommodation between a canal 12 feet in depth with one 46 feet deep, it must be remembered that whereas the Panama Canal is but 50 miles in length from deep water to deep water, the New York Barge Canal extends for nearly 400 miles. On June 22nd the first sod was turned in the work of cutting the Cape Cod Canal, which will extend for eight miles from Barnstable Bay to Buzzard's Bay. It will have a surface width of 300 feet, a least depth of 25 feet, and a high water depth of about 30 feet. The sailing distance between New York and Boston will be shortened, and vessels will avoid the perils of the outside trip around Cape Cod. Furthermore, it will serve as the first link in a chain of interior waterways by way of Long Island Sound, New York Bay, and the Raritan and Delaware Rivers to Chesapeake Bay. During the year the agitation for the construction of a waterway from the Lakes to the Gulf has been exceedingly active, although the advocates of this great scheme were discouraged by an adverse report of the board of government engineers appointed to investigate the problem. This board reported that although the construction of a 14-foot channel was feasible, there was not sufficient traffic in sight to warrant the expenditure of the $160,000,000 that the whole project would cost. The great Los Angeles Aqueduct, which, outside of the Panama and State Barge canals, is the largest hydraulic engineering work in progress, is now about half completed. This wonderful structure will be capable of conveying 230,000,000 gallons of water per day from the Sierra Nevada Mountains over the Mojave Desert to San Fernando Valley, where it will provide water for city supply, for power, and for irrigation.

Throughout the year the work of the United States government in the reclamation of arid lands has been carried on with gratifying results. This work contemplates the ultimate reclamation of some 30,000,000 acres. It is divided into twenty-eight different projects, which are scattered throughout the Western, Middle, and Southwestern States. By the end of next year it is expected that nearly 3,000,000 acres will have been brought under cultivation at an estimated cost of $70,000,000. At the present time over 1,000,000 acres are under irrigation, and upon this newly-recovered land towns and villages are springing up, and an excellent class of citizens is taking up its abode as permanent settlers. The most interesting of these works completed during the year was the Gunnison Tunnel—10½ feet by 12 feet in cross section—which has been driven through the mountain and is now being used to divert the Gunnison River into the fertile Uncompahgre Valley.

The herculean task of hewing out of the solid rock of Manhattan Island the needed space for two of the largest railway terminal stations in existence, and building within and upon them adequate train shed and terminal accommodation, has proceeded apace during the past year. The Pennsylvania Terminal is practically completed, as are also the connecting tunnels with New Jersey and Long Island. The present indications are that this great work will be thrown open for public use early in the summer of this year. The work of excavation, which had been temporarily all but suspended, on the New York Central Terminal has been prosecuted with such vigor during 1909 that all but two tracks of the old train shed have been removed and the rock excavated to about 45 feet below the street level. It is greatly to the credit of the engineers and contractors that the gradual transfer of tracks from the old to the new level has been made without the slightest interference with traffic. The difficulties of the work make it likely that three years will elapse before it is entirely completed. The extensive rapid transit system known as the Hudson Tunnels has now been opened for public service practically in its entirety, the downtown tunnels from Jersey City to Cortlandt Street having been put in service during the year. A franchise has been granted to the company for an important extension from Sixth Avenue and 33rd Street to the Grand Central Station. This important connection will enable passengers from New England to the South and West to travel by rail from the Grand Central Station to the trunk line terminal stations in Jersey City.

The close of the year witnesses the practical completion of the Manhattan Suspension Bridge across the East River, which is now spanned by four out of the five great long-span bridges of the world, the fifth being the notable Forth Bridge in Scotland. The Manhattan Bridge, which is of the suspension type, has the largest carrying capacity of any bridge in the world, provision being made for four rapid transit tracks, four surface tracks, one 35-foot roadway, and two 11-foot footwalks. The main span measures 1470 feet, and the width of the suspended floor is 120 feet. Its total cost is $26,000,000. A recent report by the engineer appointed to examine into the question of the safety of the bridge pronounced this great structure to be thoroughly adequate to carry the loads imposed. The structural modifications recommended by the commission which investigated the Queensboro Cantilever Bridge over the East River with a view to decreasing the total dead and live load have been made, and this structure also may be regarded as perfectly safe for the modified loading adopted. The commission of engineers which have the re-designing of the Quebec Bridge in hand are still at work upon the plans, and as yet no statement has been made either as to the character or capacity of the new bridge, although we understand that there is a possibility of the suspension type being adopted in preference to the cantilever—a wise substitution.

### Naval and Military.

Progress during the past year in matters naval and military may be considered as decidedly satisfactory. Several ships have been completed, chief among which are the "South Carolina" and "Michigan," the first all-big-gun battleships of our navy. These vessels, which are of 16,000 tons displacement, carry each four 45-caliber 12-inch guns. The "Michigan" on her official trial maintained an average speed of 18.97 knots. The "Delaware" and "North Dakota," dreadnoughts of 20,000 tons displacement, carrying each ten 12-inch 45-caliber guns and fourteen 5-inch guns, have passed through their trials successfully, the "Delaware," driven by reciprocating engines, averaging at full power a speed of 21.44 knots, and the "North Dakota," driven by Curtis turbines, averaging 21.83 knots. The "North Dakota" showed a higher water rate and a lower coal consumption than the "Delaware," and the naval officials are particularly gratified at the unexpectedly low coal consumption of the turbine-driven ship at cruising speed. Our third pair of dreadnoughts, the "Florida" and the "Utah," of 21,825 tons displacement and the same armament as the "North Dakota," will be launched in the spring of the present year, and work is about to be commenced upon those great ships, the "Arkansas" and "Wyoming," carrying twelve 50-caliber 12-inch guns on a displacement of 26,000 tons. Particularly gratifying has been the speed developed by our latest destroyers of the "Reid" type, the "Flusser" having averaged 32.67 knots and the "Reid" 33.75 knots in five runs over a measured mile. The vessels of this class are fine seaworthy boats of 700 tons displacement. Equally favorable results have been obtained with our latest submarines, the largest of which, the "Narwhal," has maintained a speed of 14 knots on the surface and 10 knots submerged, which performance, as far as we know, has not been surpassed in any foreign navy. During the

year the Editor had an opportunity to make a 20-mile trip in one of these vessels, and he can testify to the remarkable ease and accuracy with which the craft was maneuvered. Unquestionably submarine warfare has at last come into its own, and is destined to be a potent influence in deciding the issue of future naval operations. Lattice masts have been fitted to all of our battleships, and, as affording a fire control platform, they have proved a decided success. The gunnery of our navy continues to maintain its high excellence, and our shooting is believed to be now second to none in the world. Mention should be made of a greatly improved British torpedo, which has a diameter of 21 inches and is credited with a speed of 31 knots over a range of 7,000 yards. The increasing size of battleships has raised the question of increasing the size and draft of drydocks—a most serious consideration. During the year a contract was let for the large drydock at Pearl Harbor, Hawaii, and a new contract has also been let for the big drydock at the Brooklyn navy yard, New York. At the present time only our largest drydocks could float the new "Wyoming" over the sill at high water, and then with but a slight margin to spare.

The new 12-inch 50-caliber type gun, of the kind which is to be mounted in our 26,000-ton ships, has shown, in the Proving Ground tests, an initial velocity of 3,030 feet per second and a muzzle energy of 52,500 tons. Greatly exceeding this in power will be the new 14-inch navy gun, recently completed at the Midvale Works, which will fire a 1400-pound projectile with a muzzle energy of 65,600 tons. The new army 14-inch gun will be less powerful, but its accuracy life will be greater It will be capable of firing 250 rounds, as against 80 to 100 rounds which is the limit for the present high velocity 12-inch army gun. A comparison of the sea strength of the powers at the close of the past year places Great Britain first, the United States second, Germany third, France fourth, and Japan fifth When all ships now building are completed, Germany will be second with 820,692 tons, and the United States third with 789,687 tons displacement. In dreadnoughts Great Britain stands first with seven completed, and nine building, Germany second with two completed, and nine building, and the United States third with two completed, and four under construction Of predreadnought battleships carrying guns of 11 inch caliber or over, Great Britain has forty nine, the United States, twenty-five, and Germany, fourteen.

### Merchant Marine.

The deplorable decadence of our merchant marine has continued throughout the year, and we look in vain for any adequate evidence of the awakening of the nation to the seriousness of this pre-eminently national question. As a measure of security and defense, the existence of an adequate number of merchant ships to serve as transports and colliers in time of war is vital to the efficiency of our navy Although, during the world cruise of our fleet, the world looked on approvingly and applauded this evidence of material strength, the people who know—the naval boards of strategy and naval officers in general—must have smiled as they realized that, because of our want of transports and colliers, a voyage of this character would never be seriously contemplated by our naval board, and certainly never attempted. The signs of decadence of our merchant marine are so clearly written that he who runs may read. Within two years the number of American steamers crossing the Pacific and capable of carrying the mails has been reduced more than one-half. The year before last the Post Office Department recommended, and the Senate passed a bill providing for a compensation of so much per mile to steamers running to South America, the Philippines, Japan, China, and Australia, but the measure failed to become law. It is certain that without such federal encouragement American steamship lines will never be established, and until the construction of mail steamers and freighters is encouraged, our splendid navy will be robbed of its efficiency and limited, at least in the opening months of a war, to the defense of its own ports.

The past year will be notable in the annals of transatlantic travel for the fact that a transatlantic liner made the passage for the first time at an average speed of 26 knots an hour. This was accomplished last October, when the "Mauretania" covered the westward course from land to land in 4 days, 10 hours, and 51 minutes, at an average speed of 26.06 knots. Both this vessel and her sister, the "Lusitania," are now capable of 25 knots sustained speed in average weather and 25½ knots during the quiet weather of the summer season. Work on the two enormous White Star boats, the "Titanic" and "Olympic," has proceeded rapidly. The former vessel is already in frame, and she will probably make her first trip in 1911. The dimensions of these ships, as announced by the company, are: 790 feet over all, 92 feet beam, and maximum displacement 60,000 tons. The speed is to be 21 knots with 46,000 horsepower. The success of the turbine engine has been settled beyond all question. The substitution of four-bladed propellers of smaller diameter for three-bladed propellers on the outer shafts of the Cunarders has not only completely eliminated what vibration there was, but by improving propeller efficiency has considerably increased the speed There is no evidence that any company will attempt to rival these vessels in speed, and probably future development will be along the lines of the "Olympic" and "Titanic" These moderate-speed vessels are to be driven by a combination of reciprocating engines and turbines, the reciprocating element being used in the higher ranges of expansion, in which it is more economical than the turbine. In a recent trip to New Zealand a merchant vessel, the "Otaki," fitted with engines and turbines, made the same average speed as the sister ships "Orari" and "Opawa," fitted with reciprocating engines alone. Her coal consumption was 11 per cent less, and there was a reduction of 20 per cent in the water consumption, all three ships having the same boiler installation In this combination, when reversing, the turbine is cut out and the reciprocating engines are connected directly to the condenser Toward the close of the year two interesting devices, designed to reconcile the slow-speed demands of the propeller with the high-speed demands of the turbine, were made public. One, designed by Admiral Melville and Mr McAlpine, consists of a reduction gear of the helical type interposed between the turbine and propeller shaft. The other, designed by a German engineer, employs a form of hydraulic turbine transmission, in which the ratio of turbine speed to propeller speed can be varied indefinitely For both devices a high efficiency rate is claimed The Curtis turbine, because of its large diameter, and comparatively low speed of revolution, has less trouble from propeller inefficiency than the Parsons type The loss of the "Republic" early in the year gave dramatic evidence of the value of wireless telegraphy as a safeguard to the safety of passengers and ships. It served also to draw attention to the question of bulkhead protection Theoretically, the "Republic" should have stayed afloat long enough to be brought into port It is probable that she sank because of the gradual failure of her bulkheads, one by one On the other hand, the value of bulkhead protection was proved by the fact that the colliding ship, the "Florida," with 30 feet of her bow crushed in, was able to make port in safety An important event for the navigator was the launch of the magnetic survey yacht "Carnegie," into the construction of which no steel, iron, or other magnetic material entered She was built for the Carnegie Institution at Washington, and her surveys of the ocean will form part of a comprehensive survey of the whole world on land and sea for the determination of the exact local magnetic variations of the compass An interesting novelty in hull construction was seen in the "Monitoria," whose hull is built with large corrugations, the object of which is to increase the longitudinal strength of the ship, without increasing the weight. The extra cost is slight, and the carrying capacity is said to be increased from three to four per cent.

### Railroads

The most surprising fact in railroad development during 1909 was the continued and very considerable increase in the size of passenger and freight locomotives. So marked has this been, that we have ceased to hear anything of late about the "limits of size having been surely reached." The adoption of the Mallet articulated system has made this increase possible Two locomotives built by the Baldwin Company may be quoted as instances of this construction. A freight locomotive for the Mountain Division of the Southern Pacific Railway, built a few months ago, has 6,393 square feet of heating surface, the engine weighs 213 tons, and the engine and tender together weigh just under 300 tons. Toward the close of the year the same company built for the Atchison, Topeka & Santa Fé Railway a still larger locomotive, with 6,631 square feet of heating surface and 1,745 square feet of superheating and reheating surface, the engine alone weighs 231 tons, and the engine and tender together 350 tons. The most novel and important departure in the new passenger engines of the year is a huge Mallet 16-wheel locomotive, with two high-pressure 24-inch cylinders driving six coupled 73-inch wheels, and two 38-inch low-pressure cylinders driving four coupled 73-inch wheels. The total heating surface is 4,756 square feet, and there are 1,121 square feet of superheating and reheating surface. The engine weighs 188 tons, and the engine and tender together 305 tons. Such an engine will be able to haul the exceedingly heavy American express trains at a rate of speed equal to that of the lighter European trains Most encouraging has been the great improvement in the quality of steel rails delivered from the rail mills. Reports of the Public Service Commission of New York State show that whereas during the winter of 1907-8 there were 2,917 cases of rail failure reported, during the winter of 1908-9 the total number was 1,[illegible]—a better showing, but leaving room for much further improvement.

It is encouraging, also, to note a decrease in the number of railway accidents. This is due in some measure to the increasing application of the block signaling system, which now, except for a few short distances totaling about 100 miles, extends unbroken from the Atlantic to the Pacific coasts. Great activity is also being displayed in the development of various forms of automatic signaling, and particularly of that class of devices which acts directly on the train, and presents some visual or audible signal in the engineer's cab A device of this character for automatically and gradually applying the air brakes was recently tested on the Erie tracks with excellent results In spite of the several attempts to give it practical application, the monorail system is making but slow progress. The latest, and as far as experimental tests go the most promising, is the Brennan gyrostatic railway, which is receiving support in Europe, notably from the officials of the British army The little experimental car exhibited in the spring of 1907 has been followed by a full-sized car, weighing 22 tons and carrying a load of 40 passengers, which has made successful trips on an experimental track. The present indications are that the system may find useful application on light railways, acting as feeders to the main steam or electric lines.

### Astronomy, Photography, and Chemistry.

The year 1909 is astronomically memorable for the return of Halley's famous comet. On September 11th last, Dr Max Wolf of Heidelberg discovered this historic wanderer upon one of his photographic plates in almost the exact position which the calculations of Cowell and Crommelin called for—a feat which may be regarded as a triumph of mathematical astronomy The comet will pass perihelion on April 20th, and will be a conspicuous object in the western heavens after sunset about the middle of May, at which time the earth will pass through a portion of the comet's tail, and the comet itself will cross the sun's disk. The reappearance is therefore of exceptional interest, because it will give astronomers an opportunity of obtaining much valuable information as to the comet's structure

The year was further signalized by the discovery of another comet by Mr Daniel of the Princeton Observatory—the third he now has to his credit.

On September 24th, 1909, an opposition of Mars occurred—the most favorable which astronomers can possibly have for another fifteen years On that date the planet was distant 35,500,000 miles. Naturally, the old question of Martian habitability was revived Prof Pickering, in order to settle it once and for all, proposed a method of signaling by mirrors, and Prof Wood of Johns Hopkins University suggested a method of "winking" by means of black cloths on reels Neither astronomer probably believes in intelligent life on Mars, but was actuated solely by a desire to close a wearisome, perennial debate The theory of habitability depends very largely upon the presence of water on Mars. Dr Campbell, director of the Lick Observatory, made a careful comparison last year of the spectra of the moon and Mars. He found that there was no appreciable difference between the two, from which he infers that Mars must be practically waterless and therefore as dead as the Moon. Mr Very, of Prof Lowell's staff, on the other hand, has arrived at a directly opposite conclusion. So far from being decided, the old question is therefore more alive than ever

There were two eclipses of the Sun and two of the Moon The lunar eclipses were both total and occurred on June 3rd and November 26th. The eclipses of the Sun, occurring on June 27th and December 12th, were respectively central and partial.

As might be expected, the radio-active elements still continue to engage the attention of chemists. Although during the year 1909 no very dramatic discovery was made, Ramsay, Soddy, and Debierne made important announcements. Sir William Ramsay sealed up some radium bromide in a bottle together with water, and observed the regular evolution of the gas (hydrogen and oxygen) at the rate of 30 cubic centimeters per week. After nine months this evolution ceased almost entirely, from which Sir William Ramsay concluded that either the radium salt had lost its capacity for decomposing the water or that the velocity of the reverse action (the re-combination of oxygen and hydrogen to water) predominated over that of decomposition These results are questioned by Debierne, who decomposed water by the direct action of rays keeping the radium salt and the water in separate glass vessels Whichever chemist ultimately proves to be right, the investigation is interesting, because it is the first attempt to apply practically the enormous store of energy which is contained in radium and which may be gazed when it is stated that, during disintegration, radium emits two and one-half million times as much heat as an equal volume of hydrogen and oxygen combining explosively to form water The work of Soddy for 1909 has shown

(Concluded on page 8.)

## OXYGEN AND HUMAN ENERGY.

BY JOHN B. HUBER, A.M., M.D.

Oxygen is the life-maintaining gas. It is the most useful and the most abundant of all the elements as we still call them. Its combination with other substances—oxidation—makes heat, and that is why the sentient body is generally warmer than the atmosphere about it. All animal and vegetable life depends upon oxygen; under the sun's benignant influence the plants give out this gas which, thus freed, is respired in animal life. And by the term respiration in the physiological sense we mean not only the series of acts known as breathing, but also that in respiration oxygen is carried from the lungs by the blood, through the minutest capillaries to the uttermost cells and the most microscopic tissues of the body, giving to it strength and warmth and life.

In point of fact life itself in our present knowledge is inconceivable without oxygen, which is much more important than food to the human economy. Without the latter one may exist for months; without the former one must die within a few minutes. Consider also metabolism. Normal metabolism is the perfect chemical transformation of oxygen, fluids and food stuffs into healthy tissues. The process is a never resting, an ever changing one. Respiration provides the oxygen; ingestion provides the fluids and the food stuffs. And in that infinitely complex laboratory, the animal body, these substances are combined in the constant manufacture of fresh cells and tissues to take the place of those which are as constantly dying and being removed by way of the lungs (carbon dioxide and watery vapor) and the excretory organs.

We are thus able to appreciate one of the most valuable dicta of the evolutionists, that normal living is the right adjustment of internal relations to external relations; again, whatever amount of power an organism expends in any shape is the correlate and equivalent of a power that was taken in from without. In our physical life—as also in our psychic, for that matter—we are absolutely dependent upon a wholesome environment for wholesome existence; and by far the most essential and the most beneficent element which our environment affords us is oxygen. It is here very important to note that nature does not vouchsafe us this oxygen pure; she has tempered it for our use by combining about one part of it with about four parts of nitrogen (an inert component). Oxygen pure is irritating; and ozone, a form of oxygen in which three atoms are considered to be condensed into two—has in experiments been found so caustic as to produce pulmonary inflammations. The safest and the only good and right form of oxygen inhalation for normal creatures is in combination as it exists in the atmosphere; for this is the form to which during many ages the race has become adapted. It is possible that in other æons creatures respired oxygen under a different combination than that which now obtains; but in those æons there were no human beings—only such creatures as ichthyosauri and the dodo. No, we can live most advantageously, most wholesomely, and with the best human results only in conformity with natural laws as we find them, and with due respect and regard to our environment.

There are, however, abnormal states of the human body in which oxygenation is deficient by reason of disease processes, and in these diseases it is sought to administer oxygen in greater proportion than obtains in the ordinary atmosphere. We give it thus when oxygenation of the blood is interfered with, as in dyspnœa, emphysema, asthma, croup, whooping cough, asphyxia, tuberculosis and pneumonia, and when the oxygen proportion in the blood is poor, as in anemia, diabetes and chlorosis (the green sickness). Here Hayem's findings are, I believe, authoritative. In such diseases as those just mentioned *oxygen mixed with a determinate quantity of air* energizes to a considerable degree the nutritive functions, increases the appetite, slightly elevates the temperature, stimulates the cardiac movements and augments the bodily weight, the number of red blood cells is increased and their organic activity is stimulated, although this action is not constant, the effects may become so by the greater nutritive changes that are thus promoted."

Observe now the portion of Hayem's statement which I have italicised. In point of fact even in disease we do not, as we could not, administer oxygen pure; moreover the nurse in administering holds the tube in such manner between the parted lips that some admixture of air takes place; this admixture is essential if the oxygen is to be respired at all. Nor have I, for my part, been always sure of the efficacy of oxygen in such diseases as pneumonia. I have felt that pure atmospheric air—the colder the better its tonic properties—has been as efficacious as oxygen in cases *in extremis*. Some physicians indeed go so far as to declare that the appearance of the oxygen tank connotes the beginning of the end for the unfortunate patient.

Apparatus for registering work performed after inhaling oxygen.

OXYGEN AND HUMAN ENERGY

Nor does the oxygen tank supplied for use in the sick room contain pure oxygen. One of the firms which supplies this gas for the sick room informs me that their purest oxygen is 90 per cent, the remainder being nitrogen; that in half the cases physicians prefer and call for tanks containing oxygen compound which is made up of 60 per cent oxygen, 30 per cent nitrous oxide (laughing gas) and 10 per cent nitrogen.

I find it now very *apropos* to present certain physio-

## ELECTRICAL HEAT PENETRATION.

BY DR. [illegible]

When fever was recognized as a natural process by which the body endeavors to expel invading microbes, the idea was suggested to effect artificially a local increase in the temperature of those parts of the body which are affected by disease, thus assisting the human organism in its struggle against the morbid process. In fact, an artificial heat supply is obtained by the familiar methods of treatment which have been in use from time immemorial. However, there was so far no possibility of really permeating the body with heat, any effects being merely superficial, resulting at most in a general heating of the whole body, the excess of which is known to be counteracted by abundant perspiration and fixation of heat through evaporation.

The process described in the following paragraphs allows any part of the body to be heated to any temperature desired, producing locally fever temperatures of say 100 degrees to 104 degrees F. in order thus to increase blood circulation and to accelerate and intensify all those vital processes which are instrumental in defeating the disease. The local heating is effected by means of electric currents.

Though almost any galvanic action is attended by the production of heat, the amount of heat generated by ordinary currents is insignificant. Any attempt to produce an appreciable heating effect by the application of electricity would further have been frustrated by the small amount of energy supplied to the human body in the form of ordinary currents, while any really important increase would have resulted in a violent stimulus of the nervous system and the electrolytical destruction of tissues; intensities of 50 to 100 milliamperes thus constituted the extreme limit even in the case of small current densities, whereas twenty to fifty times as much current would have been required for the production of an adequate heating effect.

High frequency currents as lately used in connection with wireless telegraphy afford a means of applying enormous amounts of current energy to the body without any risk of injury. In fact these currents perform vibrations of such rapidity as to exceed the limits of excitability of our nervous system. The alternations in current direction also exclude any electrolytical effect.

The electrical vibrations generally used are too strongly damped to yield an appreciable effect. As in two communicating tubes a liquid removed from its position of rest will oscillate to ever-decreasing distances from its position of rest, so electric waves starting from a spark gap become smaller and smaller, and only after an interval about two hundred times as long as those vibrations will a new discharge take place and generate a new set of vibrations. In order to increase the effect of these vibrations the intervals should be reduced to about the same duration as the vibrations themselves. Their effect would then be entirely equivalent to those undamped waves which have recently been generated for the purposes of wireless telegraphy by means of highly sensitive apparatus.

A Berlin firm has recently constructed an outfit for generating high frequency vibrations, thus making heat penetration accessible to medicine as a new therapeutic method.

The most important part of the outfit, viz. the apparatus used to generate the vibrations, consists of two substantial copper electrodes separated by a small distance, between which the electrical discharges pass in an inclosed compartment. These discharges are produced by the high tension of an electrical generator connected with the electrodes, and a vibratory circuit connected up in parallel with it, and consisting of a condenser and a self-induction coil arranged in series. The condenser is charged suddenly as the apparatus is inserted, and the discharge, which ensues immediately, takes the shape of a rapidly extinguished spark between the copper electrodes. In a similar manner, as an object fixed by an elastic rubber string on being [illegible]

AN APPARATUS FOR PRODUCING LOCAL HEAT PENETRATION.

which is soon compensated by a reflux, which in its turn exceeds the normal condition, and so on Hence the processes in the vibratory circuit are comparable to an elastic pendulation.

So far from being applied directly, the vibrations generated by the condenser circuit are at first raised by induction to a convenient tension, which is graduated by shuntings from the secondary coil. The current is supplied by means of conductors to the electrode plates, to be applied to the body after first passing through an ammeter

This thermo-penetration outfit can be operated by direct connection with an alternating-current circuit, the tension being raised by a transformer before entering the generator When continuous current is used a small converter, resembling an ordinary electric motor, serves to convert it into an alternating current

## AN AUTOMATIC APPARATUS FOR PROJECTING PICTURES

BY JACQUES BOYER.

Radiguet and Massiot of Paris have patented an automatic projecting lantern, which they call the "Circus" It consists of an electric lantern provided with an endless chain of slide holders, which are brought successively between the condensing and projecting lenses by a double system of hooks During the movement of the slides, the light is automatically cut off by a shutter, so that the image does not appear on the screen until it has become motionless

The lamps are self-regulating and designed for tensions of 7, 15, and 30 volts The position of the arc is rigorously fixed and the carbons are inclined producing the maximum illumination The focal length of the condensers is about 5 inches The projecting lens can be focused by a rack and pinion, and covers a screen 3 yards square at a distance of 9 yards The mechanism is operated by an electric motor of 1/40 horsepower, placed in the base of the apparatus The apparatus is set into operation by moving a single key and the projection of pictures then continues—or may continue—as long as the carbons last or about 8 hours although the 100 slides which the apparatus accommodates are run off in from 30 to 45 minutes according to the speed to which the mechanism is adjusted. The automatic projector saves the expense of an operator and should interest all proprietors of projecting apparatus, and lecturers in general. In the theater it will replace advertisements painted on the curtain, in railway stations it may be employed to show the scenery along the line, and in newspaper offices it will prove more useful and effective than written bulletins or projecting lanterns of the ordinary type

AN AUTOMATIC APPARATUS FOR PROJECTING PICTURES.

## THE SCIENTIFIC AMERICAN TROPHY

The year 1909 has closed with only a single trial for the SCIENTIFIC AMERICAN Flying Machine Trophy That the publishers are disappointed in this lack of interest in the sport goes without saying Up to the present time Mr Glenn Curtiss to his credit, is the only American aviator who has displayed an interest in a prize which the publishers of this journal donated at considerable expense for the purpose of encouraging the development of an art which, thanks to Langley, had its scientific genesis in this country Were Curtiss our only aviator we could understand why he alone should present himself as a contestant. There are at least three other American flying-machine pilots in the field with whom Mr Curtiss would surely have coped with pleasure The conditions under which Mr Curtiss won the Trophy for the second time last year were by no means onerous. The deed of gift to the Aero Club of America provided for an annual competition by heavier-than-air machines only, with the understanding that the conditions governing the contest were to be changed from time to time so that they would keep pace with the progress made in the designing and building of flying machines. In this way it was hoped that not only aeroplanes, but other types of flying machines, such as helicopters and beating-wing machines, would receive encouragement. The conditions required at first were a straightaway flight of one kilometer (0 621 mile) in a straight line. On July 4th, 1908, Mr Glenn Curtiss carried off the Trophy by covering somewhat more than a mile in the "June Bug" In view of the flights which were then being made by French aviators the conditions were changed for 1909 to 25 kilometers (15½ miles) in a closed circuit, in other words 5 kilometers (3 1 miles) more than required in the International Contest for the Bennett Trophy Under the 1909 rules the winner for any year is the aviator who makes the longest and best flight in a closed circuit during that year In 1909 Mr Curtiss was the only competitor who came forward He easily complied with the conditions and accordingly he must be regarded as the winner of the Trophy for the year 1909 His achievement is remarkable, because he flew double the distance required in the Bennett Cup Race

The lack of entries for competition during 1909 was certainly not due to formidable conditions as the Aero Club, in establishing the rules for the year endeavored to make them so easy that any aspiring experimenter would feel that the Trophy would be well within his reach The discouraging fact remains that during the past year in spite of the notable achievements of Curtiss and the Wrights very few new men have come into the field Reports reach this office from various parts of the country that machines are being built but successful flights are few and far between In France during the past year the science of aviation has advanced by leaps and bounds as was witnessed by the successful flights at Rheims and Juvisy and by the almost daily reports of successful trials of new machines or long cross country flights by well known aviators There are fortunately a number of men in various parts of the country who are making serious experiments and it is to be hoped that great strides will be made during the year 1910 and that the competition for the Trophy will bring into the field a large number of new experimenters

Possibly the present lack of progress is due to the fact that in America at least the aeroplane is not as yet what may be called a commercial product It was not until the automobile had become a serious competitor of the horse drawn vehicle that the Bennett and Vanderbilt cups and other automobile racing trophies were earnestly competed for Perhaps the history of aeronautic sport may be the same and that when aeroplanes are manufactured wholesale the flying machine will hold a recognized position in the sport of the country In France we believe there are no less than a dozen establishments actively engaged in the making and selling of aeroplanes This placing of the flying machine upon a commercial footing undoubtedly has played its part in popularizing the monoplane and the biplane among Frenchmen For all that however there must have been popular enthusiasm before the industry could have been started —an incentive which was not that of making money We hope that in 1910 Mr Curtiss will again be a competitor that he will pit himself against men who are worthy of his steel and that a contest will be inaugurated which will arouse in this country something like the enthusiasm which was evinced at Rheims

The conditions which will govern the contests for the cup in 1910 will be announced later They will be so drawn as to keep pace with the progress made last year

SCIENTIFIC AMERICAN TROPHY

Won in 1908 and 1909 by Glenn H. Curtiss.

---

A table prepared for the Archiv für Eisenbahnwesen states that at the commencement of 1908 the total railway mileage of the whole world was 594 842 miles divided as follows America 302 938 Europe 199 346 Asia 56 284 Africa 18 518 and Australia 17 766 The cost of construction per mile has been highest in Great Britain and Ireland where it averaged $271 000 per mile in Belgium the cost was $172 900 France $122 000 Germany $108 500 Italy $12 300 Russia $79 600 per mile In the United States the average cost has been $68 800 in Canada $78 000 in New Zealand $60 300 and in Queensland Australia it is as low as $34 200

---

The boring conducted by the Prussian Department of Mines at Czuchow in Silesia had to be discontinued recently upon reaching a depth of ..40 meters In view of the fact that the cost of drilling at this depth in hard sandstone was out of proportion to the obtainable results Like the boring at Paruschowitz in Silesia which had to be abandoned at a depth of 2 003 meters on account of the drills breaking the Czuchow boring was undertaken for scientific purposes only since mining operations are of course entirely impossible at this depth, even if no account is taken of the rapidity with which the expense for hoisting increases with depth

**RETROSPECT OF THE YEAR 1909.**

*(Concluded from page 5.)*

without question that helium is produced from uranium as well as from radium, the amount being two milligrammes of helium annually from over a million kilogrammes of uranium.

In photography we find an interesting attempt to present moving pictures in colors by several inventors—Barricelli, Friese-Greene, and Urban and Smith. Curiously enough, all three inventions are based upon the same principle of so rapidly presenting images colored red, yellow, and blue that the eye has no time to notice the successive presentations, and therefore combines them into one picture In the same field of chronophotography must be mentioned the important application of the moving picture machine to the ultra microscope by Dr Comandon, an application somewhat similar in principle to the combination of the ordinary microscope and kinetoscope made by Dr Robert E Watkins of this city over ten years ago Comandon's invention promises to be of considerable educational value in actually enabling us to see the struggles of our blood corpuscles with their microbic enemies.

**Electrical.**

In view of the great advance in its efficiency, the tungsten lamp is entitled to be considered the most notable improvement of the year in the field of electricity Mention should be made, however of the important hydraulic-electric plant in Norway for reducing nitrogen from the air, which is being so successfully operated that its product is being sold in successful competition with the supply from Chili Also the calcium cyanamide fertilizer process, hitherto in the experimental stage, has, during the year, been demonstrated to be commercially practicable The Belin telephotographic process has been further improved, and in January of last year the new apparatus was successfully used between Paris and Lyons. The process of transmission is based upon the fact that a photographic plate in bichromated gelatin presents a series of elevations and depressions, advantage of which is taken for producing, by a tracing point, oscillating movements, and fluctuations in the transmission current. De Forest has improved on his system of wireless telephony as used upon our battleships during the world cruise, and a number of stations have been put in operation on the Great Lakes for communication with steamships. Communication has been established over the ninety miles separating Chicago from Milwaukee, and steamers have been in touch with the shore from a distance of forty five miles Gabet in France has achieved some success in the steering of a 29 foot torpedo by the wireless method previously tested by Tesla in this country and Armstrong in England The torpedo is driven by an internal-combustion motor, and immediately back of the explosive head is a compartment containing the wireless-controlled instruments It is claimed that the control is effective up to five or six miles. In recent tests the motor was started and stopped at will and the rudder was successfully operated from a small boat at a distance of a little over 100 yards. Mention should also be made of experimental wireless communications with a balloon, made by the United States Army Signal Corps by means of a 100-foot phosphor-bronze wire suspended below a balloon 1,000 feet in the air Communication was kept up from the Washington station until the balloon was about six miles distant, and messages were received from Annapolis over distances of from twenty to ten miles

The application of electric traction to steam railroads continues to show gratifying results. Although no figures have been made public as to its economy, the electrical operation of the suburban tracks and terminals of the New York Central and New Haven lines has been carried on throughout the year with unbroken success The New York Central electric zone is being extended to White Plains, and the New Haven Company are building a mile of experimental overhead line beyond Stamford, preparatory to the extension of the system to New Haven The latter company have also ordered two experimental freight locomotives, and it is the intention to operate the whole line from New York to New Haven, a distance of nearly eighty miles, with electric traction both for freight and passenger service The Pennsylvania Railroad Company are having fifty locomotives of 4,000 maximum horse-power built for the operation of their tunnels and terminals in New York city An important improvement in these engines is the removal of the motor from the axle and placing it above the frame, with a view to raising the center of gravity and reducing the stresses on the track and roadbed. Mention should be made here of a most important enlargement of the capacity of central power stations by the introduction of low-pressure turbines between the low-pressure cylinders and the condensers, in such power stations as are now operated by reciprocating engines. In the 59th Street power station of the New York subways the maximum output of 8 000 kilowatts of the big cross-compound engines has been increased to 16,000 kilowatts by interposing a Curtis turbine in this manner.

**Aeronautics.**

Great as was the advance made in aeronautics during 1908, it was far surpassed by the extraordinary developments of the past year, and when the history of this new art comes to be written, the sensational performances at the Rheims meet, and subsequently, will be referred to as marking the era of practical and thoroughly controlled human flight with the heavier-than-air machine. On July 30th, Orville Wright completed the government tests at Fort Myer by flying for ten miles across country at an average speed of 42.58 miles per hour with a passenger aboard, having previously made a flight with a passenger over a closed circuit which lasted one hour and twelve minutes. The government purchased the machine at the contract price of $30,000 What was probably the most popular performance of the year occurred on July 25th, when Bleriot made his successful 21-mile flight across the English Channel. At the great Rheims meet, which opened on August 22nd, no less than 38 aeroplanes were entered, of which 36 made successful flight, there being about an equal number of biplanes and monoplanes represented. Here the public witnessed the astonishing sight of as many as half a dozen aeroplanes in the air at one time, the pilots of which showed perfect control of their machines in the gusty winds that prevailed Both Bleriot and Curtiss proved how near the aeroplane had come to reaching the 50-mile-an-hour mark, the former winning the 6 21-mile race at a speed of 47 78 miles per hour, and Curtiss bringing home to America the International Cup by covering 12 42 miles at a speed of 47 04 miles per hour That the aeroplane possesses endurance as well as speed was proved by Farman, who won the long-distance race with a record of 111.88 miles covered in 3 hours, 4 minutes, 55 2/5 seconds. Subsequently to the meet, Farman, on November 3rd, at Mourmelon, France, made a bold bid for the Michelin Prize, held by the Wright brothers, by covering 144 miles in 4 hours, 17 minutes, and 53 seconds, and since, at the present writing, there is no indication that the Wrights will make an effort to retain the cup, it must perforce be returned to France During the Hudson-Fulton Celebration in New York, Wilbur Wright proved his faith in the reliability of his machine by flying from Governor's Island up the Hudson River to Grant's Tomb and back again. Early in October Orville Wright in an exhibition at Potsdam, Germany, rose to the unprecedented height of over 1,600 feet, a feat which has since been approximated by Count de Lambert, Paulhan, and Latham. Count de Lambert's lofty ascension occurred during a flight from Juvisy to Paris and back, a distance of 30 miles, during which he flew above the Eiffel Tower An encouraging fact, pointing to the more complete mastery of flight, is the increased assurance with which aviators are now making their flights under unfavorable weather conditions Instances of this occurred both at the Rheims and at the Blackpool meets, when Latham passed successfully through heavy thunder squalls and also drove his machine around a closed circuit in the face of a wind which was heavy enough at times to bring him almost to a standstill Taken altogether, it must be admitted that the honors of the year are about equally divided between the monoplane and the biplane. Future developments will be in the direction of improved devices for starting and alighting, and the introduction of some form of device for securing automatic stability. A most encouraging feature is the great reduction which had been made in the weight of the aeroplane, Curtiss's machine weighing over 450 pounds and Santos Dumont's little "Demoiselle," which is credited with a speed of over 50 miles an hour, weighing, without the aviator, only 250 pounds. On July 17th, 1909, Glenn H Curtiss, by covering more than the necessary 15½ miles in a closed circuit, won the Scientific American trophy for the second time, his first success being scored in 1908. It is a strange anomaly that there should have been but a single competitor in the country which gave birth to the successful aeroplane.

In its own field the dirigible has made proportional progress both in speed and in endurance. Count Zeppelin with his powerful dirigible "Zeppelin III" is far ahead of all competitors; and his journey from Friedrichshafen to Berlin and back, a total distance of 800 miles, was a fine performance, and redounds to the everlasting credit of the veteran inventor. Other long-distance journeys accomplished by Zeppelin during the year were a trip from Friedrichshafen to Munich, a distance of 100 miles, in 4½ hours, made with "Zeppelin I," and a journey of 150 miles in 4 hours, during which the great dirigible carried no less than 26 men.

**Automobile and Motor Boat.**

The automobile has reached such a stage of perfection that the record of improvement is confined entirely to matters of detail—no striking novelties have been developed during the year. The high-powered car is now built almost exclusively for racing purposes. For touring, a limit of 40 to 50 horse-power is found to meet the requirements of the average purchaser. The principal development has been in the increasing popularity of the low-powered car of 30 horse-power; and it is now possible to procure a 4-cylinder machine embodying all the coveted features of long wheel base, light weight, and generally smart appearance, for prices varying from $750 to $1,000. The long-distance races have waned in popularity, and such racing as is now done is confined largely to contests between stock cars on inclosed tracks. For full details of the work of the past year reference is made to our forthcoming Special Automobile Number, which will handle the subject in its usual comprehensive manner. The power boat, propelled by the internal-combustion motor, is enjoying such increasing popularity, that it bids fair to reduce the sailing yacht to an entirely secondary position in public favor Mention should be made of a very creditable experiment made by Mr. H. L. Aldrich of International Marine Engineering, who equipped a 40-foot boat with a 35-horse-power 4-cylinder producer-gas engine. Extensive cruising during the past summer proved that the boat can cover over 800 miles at an average speed of 8 to 9 miles an hour on one ton of pea anthracite coal—a truly remarkable performance. The hydroplane motor boat, of which we heard so much two or three years ago, seems destined to remain what it has always been, an exceedingly interesting curiosity As a racer it has shown high speed, but not sufficient to enable it to win against the high-powered boat of standard practice. The fastest record of the year, and a world record, was established by a 600-horse-power English boat 49.2 feet in length with two 12-cylinder Wolseley engines, which won the principal race at Monaco last year over a 62 14 mile course at an average speed of 29 15 miles per hour

**Flying-Machine Manufacture.**

Deputy Consul-General Simon W Hanauer reports from Frankfort that a limited stock company has been formed in Berlin by leading German industrial concerns for the purpose of manufacturing flying machines of the Wright system.

Wilbur and Orville Wright have given the new company, whose firm name is Flugmaschine Wright, G. m. b. H., the right to work all their patents, models, etc., for making aeroplanes in Germany The new company has a working capital of 500,000 marks ($119,000), its principal participants are Krupp Company, of Essen; A. Borsig Machine and Locomotive Works, Hugo Stinnes, coal and iron operator, Delbrueck, Leo & Co., bankers, Ludwig Loewe & Co., machine, arms, and tool manufacturers; Aerial Vehicle Company, Motor Air Locomotion Experimental Company, the General Electric Company, of Berlin, the Electro Chemical Company, of Bitterfeld. Capt von Kehler will be the managing director of the new company.

**The Aviation Meeting at Los Angeles.**

America's first aviation meet will be held at Los Angeles, Cal., from January 10th to 20th inclusive. Announcement has been made that prizes to the amount of $45,000 will be available for aeroplane contests, $22,500 for a long-distance balloon race, and $13,100 for dirigible balloon contests. Full particulars are not yet at hand, but we understand the aeroplane events will be for height, speed, and endurance. Paulhan, the record-breaking French aviator, is bringing over two Bleriot monoplanes and two Farman biplanes, and Messrs. Charles F. Willard and Glenn H. Curtiss are to make flights with the Aeronautic Society's biplane and one of Curtiss's latest machines respectively Roy Knabenshue, Lincoln Beachy, and other airship operators will compete in the dirigible contests. The meet has been sanctioned by the Aero Club of America. It offers the first opportunity Americans have had to see aeroplane contests and real flying by heavier-than-air machines.

**The Automobile Shows in New York.**

On New Year's eve the American Motor Car Manufacturers' Association will open its annual automobile show at the Grand Central Palace in New York city. This show of the "unlicensed" manufacturers will last a week. There are 225 exhibitors, and the total value of the exhibits is in the neighborhood of $1,100,000. Nearly 100 exhibitors of complete vehicles have space, while the exhibitors of parts and sundries are more numerous than ever before.

The Licensed Association of Automobile Manufacturers will hold their tenth annual show in Madison Square Garden from January 8th to 15th. The large special Automobile Number of the Scientific American will be issued in connection with the second show upon the latter date.

The gyrostatic railway car invented by Richard Scherl, a German, said to be an improvement on Brennan's car, is now in this country and will soon be given a public demonstration.

### Aviator Hamilton's Flights at St. Joseph, Mo.

After learning how to fly a Curtiss biplane and making several excellent flights at Hammondsport, N. Y., the longest of which lasted 25 minutes, Charles K. Hamilton made some daring flights at St. Joseph, Mo., recently, as detailed below by our correspondent. The machine he is using is the same one that Mr Curtiss used at Governor's Island, New York, when he attempted to fly there during the Hudson-Fulton celebration. It is fitted with a 25-horse-power 4-cylinder water-cooled motor, and the planes have a 30-foot spread. The machine weighs some 560 pounds.

The first flight at St. Joseph was made on Sunday, December 12th, over a circular course above the frozen surface of Lake Contrary After two straightaway flights of a half kilometer against the wind and a kilometer with the wind in order to test the motor, the biplane ascended in a snow storm so intense as to be blinding to the spectators. The velocity of the wind exceeded 20 miles per hour A sinuous height of 40 feet was maintained throughout the one and a half times around the course—five miles—except when nearing the Casino, a summer opera house that juts out into the lake. This forms the "aeroplane graveyard" of the course. On Tuesday, December 14th, a trial in the field inside the race track was made The wind was blowing a gale of 30 miles an hour estimated velocity A start was made over ice, snow, and weeds of the infield. The machine got off the ground under these adverse conditions, but made a 100-foot flight only. A new carbureter had been put on the engine and a 4-bladed propeller substituted for the 2-bladed one. A bad spark plug gave trouble throughout the day. Later the machine was wheeled to the lake, and a start made from the ice. The aviator feared the demolishment of the machine, and held close to the surface A piercing northwest wind swept the ice, and during the two flights a speed of 62 miles per hour was made with the wind while flying near the west shore The timing was done by Mr J H Hess, and the distance was measured by your correspondent.

Wednesday was a day of failure, owing to motor trouble and unfavorable winds, until a late hour in the afternoon, when two trials were made over the field within the race track. The first was a very short flight, and the second resulted in breaking two support braces of the horizontal rudder The manager of the flights appointed by the Retail Merchants' Association insisted that the starts be made from the field within the race track This was an undulating surface covered with ice and snow, and only 1,250 feet long.

On Thursday, after the 2-bladed propeller had been replaced and the old carbureter reinstalled, the machine was taken to the lake once more A stiff north west gale delayed flight until late in the afternoon Two flights, or rather a series of short flights, were made. A circuit of the course was accomplished with numerous touches. Only three cylinders were firing part of the time, and at these intervals the machine touched the ice The motor finally failed altogether, and the machine was stopped so suddenly by the application of the brake that it skidded completely around on the ice This resulted in breaking the cement of the tires and almost ripping them off Later, when the second flight began, after covering 600 feet the motor started missing, and while passing through a snow drift two tires were thrown, locking one wheel, but notwithstanding this, the machine again rose and covered 1,000 feet The motor picked up in the meantime. Altogether, some remarkable feats were accomplished.

The flight on Sunday, December 12th, was discontinued owing to inability to see, the fast-falling snow having formed ice upon the aviator's goggles. This flight was made in private, and was not witnessed by many people

On Sunday, December 19th, aviator Hamilton made his longest and best flight at St. Joseph. He circled above Lake Contrary for twelve minutes. The flight was witnessed by 600 interested spectators

## Correspondence.

### Speed of the "North Dakota."

To the Editor of the Scientific American

Following closely on the heels of the article in the Scientific American giving the new U S. battleship "North Dakota" the proud title of "Fastest Dreadnought Afloat," there appears in the columns of a Canadian publication of the first class a statement to the effect that British "Dreadnoughts" are known to make an average of over 23 knots an hour, while the maximum average made by the "North Dakota" is below 22 knots an hour

If the exact figures relating to Great Britain's naval affairs are not very generally known, may it not be that she, perhaps more wisely, prefers not to publish to the world her naval secrets, while Americans, in justifiable pride over their achievements, are making ill-advised haste to claim the first place in the progress of naval science. We have a right to expect the perfection of accuracy in all matters treated of in the pages of the Scientific American M W

Stanstead, Quebec.

[The "Dreadnoughts" referred to as making over 23 knots are probably the cruiser-Dreadnoughts of the "Invincible" type The "North Dakota" is of another class.—Ed ]

### Effect of Earth's Rotation on Gyroscopic Cars.

To the Editor of the Scientific American

I take much pleasure in reading your paper, and being a railroad man, was especially interested in the article describing the monorail car I have seen the gyroscope principle, for balancing such a car, discussed numerous times, but there is one point regard ing gyroscopes which I have never seen mentioned in connection with this scheme.

It may not be of much importance, but it is nevertheless interesting, to note that a gyroscope does not retain its balance relative to the earth, but relative to a fixed point in space In other words, it would appear that on a "mono-railroad" running north and south a car would be tilted to the west at the rate of fifteen degrees per hour, or one degree every four minutes, due to the rotation of the earth

Of course, this is not fast enough to inconvenience anything, and perhaps Mr Brennan has provided a way to overcome this difficulty, but if not, it would be interesting to hear what others have to say in regard to this.

At any rate, a solution of this problem would be more interesting and of more practical benefit than the computation of our ancestors For the monorail appears like a great improvement over the double-rail system for economical and rapid transportation In fact, for light, high-speed passenger and express traffic, it would seem as if there is a great future in store for the monorail. T E Baker.

Lockwood, Ohio.

### Safety in Mines.

To the Editor of the Scientific American

I noticed in a recent issue of your valuable journal a suggestion for the better safeguarding of the lives of coal miners. As this suggestion was on the lines of ideas that I have for some time entertained, I would like to amend your suggestion by an addition

I believe that stations of refuge, provided with fire and gas-proof doors, should be established in various places in coal mines, and that these stations be provided with two tubes or casings driven from the surface by well-driving machinery This would allow an air, food, and water supply to be maintained indefinitely, whether or not it should be necessary to seal the mine for the purpose of extinguishing fires Of course, it would be necessary to equip each of these stations with telephone and possibly lighting facilities, and of course, with facilities for forcing air into one of the pipes.

I am assuming, without having made figures on the proposition, that sufficient air to supply a considerable number of men could be forced through a six-inch tube by sufficient pressure.

I believe it should be compulsory that mine operators should provide some stations which would prevent such appalling calamities as the recent one at Cherry, Ill., and with this or some similar plan the cost would be so slight that it would be practicable to carry the same into effect. Alex. T Brown

Syracuse, N. Y

### Emergency Shafts for Mines.

To the Editor of the Scientific American

As a further safety precaution in the operation of mines, I would suggest the drilling of large holes, as many as may be necessary, from the surface to the main arteries of the workings, up through which, in cases of disaster such as the recent one at Cherry, Ill., men could be drawn to safety. Seventeen-inch holes are now quite common in the oil country, and larger ones could be drilled if necessary. These holes could be located at different advantageous points, and terminate in rooms in the mines or alcoves cut at the sides of entries in such a location as to not interfere with their daily use Slings made of chains, four chains, 30 feet long, spaced equally around a circle the size of the hole, and attached to an iron ring or spider at their upper ends, five small circular platforms of strong wire mesh, spaced six feet apart, inside these chains, would make what could be termed a five-storied elevator cage that would haul five men or ten boys up at a trip.

Such a cage could be galvanized for durability, would be strong, and not weigh over 150 pounds. There could be handholds placed under each platform for the men to grasp to steady themselves These cages would collapse when they would strike the bottom and could be quickly loaded, a man stepping on to each platform as it would be slowly raised, and when loaded, could be quickly hoisted to the surface A perhaps better cage could be made of strong wire mesh, platforms and all but would have to be made to descend into a sump drilled deeper than the bottom of the mine, so that it could be loaded as it was raised.

The hoisting drum on the surface could be operated by steam, air, electric, or even horse power The latter would have been invaluable at Cherry, Ill, as there would have been ample time for even a slow-operating apparatus to have saved all able to get to it, but an electrically-driven hoister would be preferable to any other Wires from the power house could be run to each hoister, and proper inspection would insure the apparatus to be in working order, if it should be needed

Air could be blown down these holes for the supply of the men at the bottom, even if the cages were being used, the wire mesh construction of them allowing its passage Water, food, oil for light, etc, could be sent down through the holes, and even doctors with medicines

The holes could be left open at all times for ventilation, but if such would interfere with the working of the fan currents and other ventilation systems of mines, the holes could be kept closed at the top by a proper batten If water from the wells would drip down and interfere with the working of mines, the holes could be plugged at the bottom by means of an oil well packer or similar device which, while perfectly water tight, can be quickly removed, leaving the hole clear

I can see no reason why this plan of rescue in cases of mine disasters would not be entirely practicable and effective, even in mines of one thousand or more feet in depth. Edward Rowe

Indiana, Pa.

### The Current Supplement.

An illustrated description of the large double-deck bridge which has been constructed over the River Wear to accommodate both railroad and highroad traffic is published in the current Supplement, No. 1774 "A Log Box and How to Make It" is the title of an article which will undoubtedly be read with interest by amateur mechanics. Up to a few years ago water powers were easily bought for a song Nowadays they have so definite a value that the matter of ascertaining their actual horse-power is of considerable importance Mr W T Ryan explains how this calculation is made Robert M Strong's excellent comparison of gasoline and alcohol engines is continued The comet families of Saturn Uranus and Neptune are discussed by H C Wilson. L H Baekeland describes the use of his newly invented substance "bakelite" for electrical and chemical purposes The kinetoscope has entered a new field It now shows us moving pictures of a world which is invisible to the naked eye and revealed only by the ultra microscope, all of which is explained in the current Supplement James Scott writes on microscopic tree fungi The efficiency of modern aeroplanes is discussed by G Garnier on the basis of the results obtained at Rheims

### A Correction.

In an article on page 462 of the Scientific American of December 18th, 1909 it is stated that by the interposition of a turbine between the low-pressure cylinders and the condenser of the cross-compound reciprocating engines in the 59th Street power station an additional 8,000 horse-power was secured The item should have read an additional 8,000 kilowatts. The maximum economical output of these engines is now 8,000 kilowatts developed in the reciprocating element and an additional 8,000 kilowatts in the turbine making a total of 16,000 kilowatts or say about 22,000 horse-power for the whole engine

The Municipal Art Commission of New York has just published a catalogue of the works of art belonging to the city of New York It is a book of 240 pages, and contains more than 100 illustrations reproducing the works of art scattered around the city

## THE GREAT ST. BERNARD HOSPICE

BY SAMUEL J. SHEPSTONE.

The St. Bernard Hospice stands some 8,120 feet above the level of the sea on a mountain pass which forms one of the principal highways between Switzerland and Italy. Over 20,000 persons cross this road every year, and as nearly two-thirds of this number accomplish the journey in winter, the monks and dogs of the hospice, whose mission it is to aid these travelers, may be said to be responsible for many lives every year.

The hospice can claim to be one of the oldest institutions in Europe. It was founded as far back as 962 by Bernard de Menthon for the benefit of pilgrims journeying to Rome. For many years after it was first erected it was subjected to frequent attacks by bands of mountain robbers. Often the brave monks were forced to barricade themselves in their stronghold until stress of weather drove the besiegers away. Once the hospice was destroyed by fire. Here Napoleon was received when he took his army over the Alps into Italy in the spring of 1800. His forces numbered 30,000 men, and for miles they had literally to fight their way foot by foot up the steep mountain pass, often waist deep in snow. Napoleon converted the hospice into barracks; the great guest room where travelers are now sheltered into a huge hospital ward.

When first seen, the monastery, from an architectural point of view, is disappointing. It consists of a plain block of gray buildings with massive walls built to resist the wind and the weight of snow. In midwinter the snow around the buildings is seven to ten feet deep, and sometimes forms drifts against the edifice that reach right up to the roof. If the exterior is disappointing, the same cannot be said of the interior. On the side reserved for the better class of travelers there is a spacious dining room containing a handsome piano presented to the monks by King Edward, while the bedrooms with their spotless curtained beds are the essence of comfort. Anyone crossing the pass is at perfect liberty to enter the hospice and accept its hospitality. No traveler is ever turned away. Two good meals are served every day, namely, at 12 noon and at 6 P. M. At these meals representatives of almost every nation on earth may be seen. Italians naturally predominate. Next come Swiss, then Russians, Germans, French, Turks, Spaniards, English, and perhaps two or three American travelers. The food is plain but good and plentiful, and the beverage served is the famous red wine of Piedmont. After meals travelers spend their time much as they wish, in easy conversation with one another, in games, in reading the books in the library, or in inspecting the curios in the museum.

Not so long ago the hospice was put into telephonic communication with the outside world, with the result that the work of the monks has been lightened and that the number of lives lost has been reduced to a minimum. The monastery is connected by telephone

Looking for bodies in the snow after an avalanche.

St. Bernard dog with flagon of wine.

with a small inn on the Swiss side and with St. Remy on the Italian side. At both these stations arrangements are made by which the monastery is warned of the number of persons that commence the ascent from these two places. Through these advices the monks know exactly how many travelers are making the ascent from either side of the mountain. It is really impossible for anyone to attempt to make the ascent without the monastery being warned. Often a party of travelers set out for the hospice in fine weather. A few hours later a sudden storm comes on, and the monks, knowing at what time the ascent was begun, know approximately what spot the travelers should have reached. At the hospice a book is kept recording the telephone messages, and also the number of travelers that reach the summit, so that at any given moment the monks know the exact number of people on the pass and their approximate whereabouts.

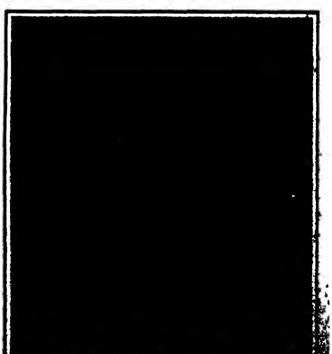
Only a few weeks ago a message was received on the telephone that three men, two women, and one child had started up the path. The weather was unsettled at the time, and two hours later a blinding snowstorm came on. At once two of the brethren accompanied by two dogs hastened down the pass to look for the travelers and guide them to the hospice. They knew about where the travelers should be, and were surprised that the dogs failed to scent them. After nearly two hours of fruitless search a dog arrived from the monastery. He carried a message to the effect that after they had left, a telephone message had been received saying that the travelers had returned to the inn.

When speaking about the dogs, M. Bourgeois, the present provost, and his principal assistant, Father Jules Darbellay, to whom I am indebted for the information contained in this article, assured me that the wonderful stories that have been told about the sagacity of the dogs are not exaggerated. Near the hospice is a monument to Barry. This dog saved forty lives in a period of ten years, and then was accidentally killed.

In the kennels at the hospice there are at the present time fifteen trained dogs and an equal number of bitches and young puppies. They were all born at the monastery. Their training is very simple. During the summer months, when the monks are not so busy, they take the young dogs out in the valleys or hollows where there is always snow. One man then lies down in the snow or buries himself in it. A dog is sent to look for him. He is taught to bark when he has found the man, and also to rouse him up from sleep by licking his face. When the man wakes up and stands on his feet, the dog leads him to the hospice, running on in front to show him the way.

According to the traditions of the monastery, the St. Bernard is a cross between a Danish bull bitch and a mastiff, a native hill dog, though at what time the cross was effected it is impossible to say. After the breed was once established it was kept pure until 1812, when, owing to the severity of the winter, the monks were obliged, contrary to their usual custom, to send out the brood bitches as well as the dogs, with the result that all the females succumbed to the cold, and the monks found themselves without the means of continuing the pure breed. In this extremity a cross with the Newfoundland was tried, but at first failed owing to the excessive coat of the Newfoundland, which hampered the dogs in the snow; however, by breeding back to their own short-coated dogs, the

The interior of the chapel.



[illegible]

THE GREAT ST. BERNARD HOSPICE.

monks obtained the desired shortness of coat, though occasionally specimens were born with the rough coats These rough-coated animals were sold or given away to the inhabitants of the surrounding valleys, who continued to breed them so that St. Bernard dogs soon became general in Switzerland. The full grown specimens in the kennels at the hospice are magnificent creatures of their kind They stand thirty inches high at the shoulder and weigh about one hundred and fifty pounds. They are exceedingly strong and can carry a man for a considerable distance By nature they are gentle except in the puppy season when the mothers are apt to resent attentions.

This band of faithful creatures commence their work in earnest at the end of September and continue looking for lost travelers right on to the middle of June which period represents the winter season on the pass In the depth of winter not a vestige of a path is visible The snow drifts too present formidable obstacles Besides there is the danger of avalanches Fogs are frequent and in stormy weather the wind rises to a hurricane blowing the snow into one s eyes and making it impossible to see any distance ahead.

Great St. Bernard hospice in winter Such snowdrifts are not extraordinary in the Alps.

Entrance to the St. Bernard hospice

Indeed the monks will not hesitate to tell you that during the winter months it is impossible for an inexperienced traveler to venture upon the mountain and safely negotiate the pass without receiving help

Considering the perils of the road one may well ask why people venture upon it during the winter The fact is the greater majority are poor workmen going or returning from their labors on the other side of the Alps In February and March as many as a hundred will make their way across the pass in a single day It is then that the monks are busy They think nothing of remaining out in the snow seeking the lost, for twenty four hours at a time Father Darbellay told me that he has known the dogs to remain out in the snow for two days eating very little and not taking any rest or sleep

Before the advent of the telephone the dogs carried a flagon of wine tied to their collars and food strapped to a saddle on their backs. Now they carry only the wine because it has been found that the weight hinders their progress through the snow So well are they trained, that they are often dispatched by themselves down the pass to escort travelers up the treacherous path to the hospice They always discover them and guide them to the desired haven. In the same way the monks will allow the dogs to accompany the travelers on their journey down the mountain if the weather is at all bad and the road difficult to trace If a traveler is found in an exhausted condition he is conveyed to the monastery on an improvised stretcher Should it prove that help has arrived too late the body is left strapped to the board and placed in an upright position in the mortuary chapel by far the most gruesome place in the whole monastery Through the low latticed bars of the windows one can gaze at the dead within The keen air sweeping from end to end preserves these poor relics of humanity for years in a semi mummified condition, and unless they are identified there they remain. At the present time there are some twenty bodies in the mortuary, one of which is said to have [illegible]

[illegible]

tions There are over one hundred beds for travelers and they are never empty during the winter months Often the monks are called upon to find shelter for as many as three hundred or four hundred persons at one time No one is asked to pay for his accommodation Very few drop in the alms box in the beautiful chapel the amount that would have been paid for similar accommodation at an ordinary hotel Hence the monastery must depend to a very large extent upon other means of support Unfortunately too the expenses are very heavy for almost all supplies have to come from Aosta and the neighboring villages The monks have a deep cellar where they keep their wines unfrozen Fresh meat is procured from the valleys in summer but for the winter the priests lay up a store of salted meat They also keep a number of cows in the summer to supply them with milk butter and cheese but only one cow is retained in the winter Wood for firing is one of the most important necessaries Not a stick grows within seven miles and all the fuel has to be brought from a forest on the backs of horses For this purpose alone about thirty horses are employed daily during the brief summer

The following notes concerning the storage of California or crude oil in concrete reservoirs were recently given in Concrete A 1 000 000 barrel reservoir lined with concrete has recently been completed at Port Richmond Cal and one of 800 000 barrel capacity is under construction near Bakersfield The practice is to excavate the earth which in most fields is a sandy loam porous and very dry to about one third the depth of the proposed reservoir With the material removed a levee is built round the excavation having side slopes of 1 1½ on both faces The bottom and sides are then covered with about 3 inches of concrete often reinforced with expanded metal or some equivalent Small cracks that occur at the junction of the sides and bottom and along the line between the cut and the embankment soon become filled with sediment and are believed to permit the leakage of very little oil

A number of such structures in Southern California have recently been examined and no signs of depreciation in the quality of the concrete were found even in those which had been in use for a considerable period

## THE HEAVENS IN JANUARY

BY HENRY NORRIS RUSSELL, PH D

AS we watch the brighter stars on a clear winter's night we may well be impressed with the notable differences in color among them What may strike us first is that a very bright star like Sirius when low on the horizon visibly changes color from moment to moment This is like its twinkling purely an effect of our atmosphere whose refraction changing slightly as masses of air of different density are carried across our line of sight by the wind causes now one color now another to be strengthened for an instant in its spectrum while others may be for a moment almost absent

But when the stars have risen high and the night is clear and calm so that these disturbances are no longer perceptible the differences of color persist

Sirius is brilliantly white and so are most of the stars of Orion Capella (whose light much resembles that of our sun) is clearly yellow Aldebaran is orange red and Betelgeux redder still The fainter stars whose light is too weak to show much color to the naked eye when examined with the telescope show similar differences in hue

The cause of these phenomena so easily observable must be sought in the stars themselves Recent physical research has made it almost certain that we may find it in their temperature

If we take a solid body such as the carbon filament of an incandescent lamp and heat it up gradually to higher and higher temperatures which in this case we may easily do by increasing the electric current—we will observe that when it first becomes visible its light is of a dull red As the current is increased the light becomes very much brighter and yellow instead of red

If finally we apply a very high voltage and put through the lamp a heavy current which it can stand only a short time without breaking down it will give for the moment an intense white light far whiter as well as far brighter than under ordinary conditions

All incandescent solids or liquids behave in the same way and careful work both in the laboratory and on theoretical lines has led to a formula (too complicated to be given here) which enables us to tell just how much light of any given color (or wave length) will be given off per square inch of surface at a given temperature We cannot of course experiment with temperatures as high as those that prevail upon the sun but there are good reasons to suppose that the formula fits the facts very closely even in this case

We may illustrate its results by an example Consider a star of the same temperature as the sun and suppose that we observe it (1) through deep red glass which transmits only the extreme red rays (2) through a yellow glass transmitting only the yellow and green light (3) by photography when the violet rays are alone effective Now suppose its temperature suddenly doubled Our formula tells us that through the red glass it will look about seven times as bright as before through the yellow glass more than ten times and by photography some twenty times as bright

If on the other hand its temperature was reduced to half its initial value its light would fall off much more rapidly the red to 1/40 the yellow to 1/100 and the blue to but 1/400 of its original amount

Suppose now that we had three stars close together in the sky whose surfaces were at the three temperatures just discussed Which of them will look brightest to us will depend on how big they are and how far away Let us suppose that, viewed through the yellow glass, they all seem equal in brightness, in which case the hottest one must of course be much smaller or much more remote, than the coldest.

From the numbers just given we can deduce that, when seen through the red glass the hottest star will seem but 70 per cent as bright as the one which resembles the sun and the coldest star twice as bright as this standard of comparison. On the photograph the disparity will be even more marked The hot star will appear twice as bright and the cold star only one-quarter as bright as the one of the solar type

We have thus a means of determining their temperatures even though we do not know how far off they are nor what is their actual brightness by comparing their relative brightness in light of different colors

An extensive series of observations of this sort have recently been made at Potsdam by Scheiner and Wilsing using apparatus of high precision and great care to avoid all sources of error and employing five different colors of light so that the comparison of the values obtained from them might serve as a check not only upon the accuracy of the observations but of the formula used in calculation

The results are highly satisfactory and form an important contribution to our knowledge of the stars

As is obviously to be expected from what has been said the white stars are the hottest The average temperature of those observed comes out about 11 500 deg C just about double that of the sun

The average temperature which they calculate for a number of stars whose spectra resemble the sun's is 5900 deg—a little higher than that of the sun itself That of the stars which resemble Arcturus in spectrum is 4200 deg and that of the reddest stars like Betelgeux about 3300 deg—lower than that of the carbons in the electric arc (The arc light of course looks far bluer than most stars but this is because much of its light comes from hot carbon vapor which like the mercury vapor in the now familiar lamps gives off strongly colored light of its own in this case violet )

A rather faint telescopic comet was discovered by Mr Daniel at Princeton on the night of December 6th It was then about fifty million miles from us and very close to perihelion It is now slowly receding from earth and sun but will remain telescopically visible until the end of January or later

Halley's comet though well placed in the evening sky in Pisces not far from Mars and Saturn will probably still be much too faint to see without a telescope

### THE HEAVENS

The finest region in the starry sky is now well seen in the southeast. High up, almost overhead, is Taurus, marked by the group of the Pleiades and the red Aldebaran. Below is the splendid Orion, and beneath him Canis Major with the incomparable Sirius.

East of the zenith is Auriga with the great golden star Capella. Below are the Twins, and on the right Procyon The faint star cluster Praesepe marks the place of Cancer and on the horizon are Hydra and Leo partly risen

The constellations in the southwest are much less prominent. Aries which is high up can at once be recognized by the peculiar small triangle formed by its three principal stars the faintest of which γ is a fine double Our initial shows how ridiculously little resemblance there is between the figure of the Ram and the stars which bear his name

Eridanus Cetus and Pisces are none of them very bright but the planets Mars and Saturn which are close together in the last are conspicuous. The very brilliant object in the southwest early in the evening is the planet Venus.

Pegasus and Andromeda are well seen in the west Perseus is right overhead and Cassiopeia Cepheus and Cygnus occupy the Milky Way as far as the northwestern horizon Ursa Minor and Draco are under the pole and Ursa Major is coming up in the northeast.

### THE PLANETS

Mercury is evening star until the 26th when he passes between us and the sun and becomes a morning star He is well visible during the first half of the month especially about the 10th when he sets about 6 15 P M He is then in Capricornus far from any bright star and should be easily identified

Venus is exceedingly bright and conspicuous especially at the beginning of the month when she sets about 8 10 P M By the end of the month she has come nearly into line between us and the sun and is less prominent setting about 7 P M but is still far brighter than anything else in sight

Mars is in Pisces at the beginning of the month close to Saturn and gradually moves eastward into Aries He is in quadrature with the sun on the 17th and is on the meridian at 6 P M Viewed telescopically he shows a marked gibbous phase—like the moon three days from full

Jupiter is in Virgo and rises about midnight being in quadrature with the sun on the opposite side from Mars on the 4th Saturn is almost opposite him in the sky in Pisces and is visible in the evening almost till midnight

Uranus is in conjunction with the sun on the 11th and is invisible throughout the month Neptune is in opposition on the 8th and is visible all night long He is then in R A. 7 h 17 m 28 s declination 21 deg 32 min N and is moving 7 1 s to the west and 14 sec. northward daily His motion alone serves to distinguish him from the stars unless one has a telescope powerful enough to show his disk

### THE MOON

Last quarter occurs at 8 A M on the 3d new moon at 7 A M on the 11th first quarter at 5 A M on the 18th and full moon at 7 A M on the 25th. The moon is nearest us on the 17th, and farthest off on the 4th and 31st.

She is in conjunction with Jupiter on the 3d Uranus on the 11th Mercury on the afternoon of the 12th, Venus on the 13th Saturn on the 17th Mars on the 18th, and Jupiter once more on the 30th.

The memory of the late Capt. Charles W Gridley, who was Admiral Dewey's flag officer on board the cruiser Olympia at the battle of Manila Bay in 1898, has been honored by a bronze memorial tablet which has been placed on the wall of Memorial Room in Bancroft Hall Annapolis, Md. The funds were procured by popular subscription

### THE RIGNOUX-FOURNIER SYSTEM OF TELEVISION

BY FERNAND HONORÉ.

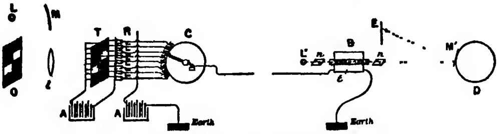
In the present state of science, the solution of the problem of vision at a distance by means of electrical transmission appears to be only a question of money. Researches in this field are directed toward the utilization of a peculiar property of the element selenium, which conducts electricity more or less readily in proportion to the intensity of the light which falls upon it. Upon this property is based the system of electrical transmission of photographs which was invented by Prof. Korn, of Munich, and which has for several months been in regular operation between the offices of the Daily Mirror in London and L'Illustration in Paris. The general arrangement of Korn's apparatus has already been described in the SCIENTIFIC AMERICAN. The photograph to be transmitted, a negative film, is wrapped round a cylinder which is caused to rotate before a source of light so arranged that only a very small area of the photograph is illuminated at a time. The pencil of light after traversing the film falls upon a cell of selenium forming part of an electrical circuit which extends to the receiving station. Owing to the property of selenium mentioned above, the current which flows through this selenium cell at any instant is proportional to the transparency of the negative film at the point traversed by the pencil of light at that instant. At the receiving station this fluctuating current is employed to uncover to an extent proportional to the instantaneous strength of the current a lens which conveys a beam of light upon a photographic film carried by a cylinder which rotates in synchronism with the cylinder at the transmitting station. Hence the part of the film on which the beam falls is illuminated and consequently blackened to a degree proportional to the transparency of the corresponding part of the original film. In short, a negative at one station produces a positive picture at the other by the successive transmission of many small parts.

Instead of prolonging the operation in this manner let us suppose that it is all done at once. Let us project the image upon a sheet of selenium divided into a very large number of small cells, each of which is connected with the receiving station by a separate wire. It is evident that in this way the entire picture could be transmitted at once and consequently that electrical vision at a distance could be realized. But in order to accomplish this thousands of wires, each connected with appropriate apparatus, would be required and the expense incurred would probably be out of all proportion to the value of the results obtained.

This theoretical scheme has not formed the basis of any practical experiments which have yet been brought to public notice. It was announced a few months ago that E. Ruhmer, the well-known electrician of Berlin, had solved the problem and that his apparatus, costing an enormous sum to construct, would be the principal attraction at the Exposition at Brussels in 1910. No details of the apparatus, however, have been published. We know that it employs selenium, but we do not know whether it uses one wire or many wires.

In this state of the problem it seems particularly interesting to note the solution proposed by two French inventors, M. Rignoux and Prof. Fournier, some of whose experiments the writer has had the good fortune to witness.

Rignoux and Fournier have invented two types of apparatus. The first is designed merely for demonstration and necessitates the employment of many wires. It may be described briefly as follows: At the transmitting station an object (a large letter of the alphabet, for example) is strongly illuminated and its image is projected by a lens upon a frame containing a number of selenium cells, each of which is connected with the receiving station by a separate wire. Each cell, and its wire, transmits a current proportional to the brightness of the part of the image projected on that cell and the corresponding part of the object. At the receiving station these simultaneous currents of unequal intensity traverse an equal number of little coils, and thereby uncover the same number of little mirrors to an extent proportional to the strengths of the various currents. Beams of light reflected by these mirrors are projected on a screen, side by side, forming patches of various degrees of brightness, proportional to that of the corresponding parts of the object. With a very large number of selenium cells, wires, coils, and mirrors it would be possible to transmit a picture with fine detail and many gradations of tone. The experimental demonstration, which is actually made in summary and crude, but quite convincing. The multiplicity of wires is a serious defect, which the inventors believe they have found means of remedying in their second apparatus, which is in course of construction and is illustrated by the accompanying diagram. At the transmitting station the rays of the luminous source $L$ are reflected by the mirror $M$ upon the object $O$, the image of which is projected by the lens $l$ upon the frame of selenium cells $T$. (The diagram shows a frame of eight cells and an object divided into eight equal squares. Two of the squares are white and their images illuminate the two corresponding selenium cells.) The very weak currents transmitted by the selenium cells are sent into the relay $R$, where they set into motion much stronger currents, the intensities of which are proportional to those of the selenium cell currents, to the illumination of the respective cells and to the brightness of the corresponding parts of the object.



THE RIGNOUX-FOURNIER SYSTEM OF TELEVISION.

The problem is to transmit all of these currents through a single wire without confusion and to receive them and cause them to act separately and simultaneously at the receiving station. For this purpose Rignoux and Fournier have devised the following arrangement: The currents are conveyed to the contact pieces of the collector $C$, from which they are taken successively by a rapidly rotating wheel which is connected with the receiving station by a single wire.

Let us for the moment disregard the question of speed of transmission and consider the means by which these successive currents are received.

At the receiving station the light of a source $L$ polarized by its passage through the Nicol prism $n$ traverses the tube $t$, which is filled with carbon disulphide, and then falls upon a second Nicol prism $n'$, which is crossed with regard to the first prism. The tube is surrounded by a coil of wire $B$, which is connected with the wire coming from the transmitting station. Hence the currents which traverse the selenium cells for the transmitter flow successively through this coil and produce an electro-magnetic rotation of the plane of polarization of the light which is passing through the carbon disulphide to a degree proportional to the illumination of the particular selenium cell which is momentarily connected with the line wire, causing corresponding fluctuations in the intensity of the light which emerges from the second Nicol prism $n'$. This beam of light of varying intensity falls upon the cylinder $D$, which rotates in synchronism with the collector $C$ at the transmitting station, and which carries a number of mirrors $M'$, equal to the number of selenium cells. Hence each mirror reflects a quantity of light proportional to the illumination of a particular selenium cell and the brightness of the corresponding part of the object. The mirrors are so arranged that the light reflected by each falls on a different part of the screen $E$, on which is thus produced a mosaic picture formed of patches of various degrees of brightness of the object exposed at the transmitting station.

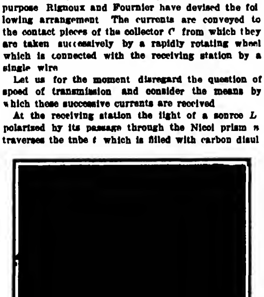
It is possible to transmit and make visible in this manner, employing a single wire, an image produced by several thousands of selenium cells? Yes. There is no difficulty in constructing a frame of 10 000 or more selenium cells, each connected by a separate wire with a collector which comprises an equally large number of contacts. Now if we remember that the frequency of alternation of an alternating current often exceeds 100 000 cycles per second, it becomes evident that 10 000 currents can be collected and transmitted successively over a single wire in a small fraction of a second. By the employment of 10 000 mirrors at the receiving station an image composed of 10 000 patches of light can be projected within the same fraction of a second. The different parts of the picture will really be projected successively, but they will appear to be simultaneous owing to the persistence of impressions on the retina of the eye if the projection of the entire picture is accomplished within 1/40 second, and the apparatus can be so constructed that this process will be repeated indefinitely, giving the appearance of a persistent picture instead of a fleeting glimpse.

Hitherto we have supposed the number of mirrors to be equal to the number of selenium cells. It may be found possible, however, to diminish the number of mirrors and to operate each mirror successively by the currents from several cells. This modification would doubtless involve complications and difficulties in construction which we need not discuss. For the present it suffices to show that the problem of vision at a distance by means of a single wire connecting the two stations has been solved by MM. Rignoux and Fournier. In the practical realization of the desired result the inventors will have to reckon with the phenomena of self-induction, interference, and the electric inertia of selenium, but these are familiar technical difficulties which will sooner or later be surmounted.

---

### DAVID STARR JORDAN

BY MARCUS BENJAMIN, PH.D.



The New President of the American Association for the Advancement of Science.

The distinction of studying natural history under Louis Agassiz in the laboratories in Cambridge is one to be highly appreciated, and of the many eminent naturalists who were so fortunate as to receive their first inspiration under the guidance of that renowned master, many if not most have ceased their activities. Of the earlier students Brooks, Hyatt, and Packard have joined the silent majority. Alexander Agassiz, Putnam, Scudder, and Verrill are fortunately still with us in the happy possession of an assured fame. At the close of the elder Agassiz's career he established a summer school on Penikese Island, and of those who studied there two have achieved especial distinction: Richard Rathbun, the Assistant Secretary of the Smithsonian Institution, who is now directing the activities of a score or more of younger men in the work of the National Museum; and David Starr Jordan, who presides over the destinies of the great Stanford University in California. Prof. Jordan has been called to preside over the meeting of the American Association to be held this week in Boston, and of him is the following brief sketch.

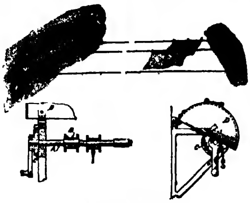
David Starr Jordan was born in Gainesville, New York, on January 19th, 1851, and grew up on his father's farm in Wyoming County, receiving his early education in schools in the vicinity of his home. In 1868 he entered Cornell, and there devoted himself to scientific studies, developing a special interest in botany, in which branch he was made instructor in his junior year, and continued to hold that place until he was graduated with the degree of M. S. in 1872.

He was called to the chair of natural history in Lombard University in 1872, a place which he held for a year, and then accepted the principalship of the Appleton (Wis.) Collegiate Institute. He then entered the Anderson School on Penikese Island as a student and lectured there on marine botany during the summer of 1874. It was there that he came under the influence of the elder Agassiz and began his studies

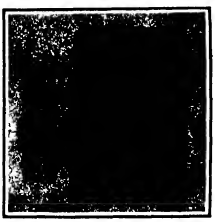
(Continued on page 16.)

### CLOTHES-LINE HANGER.

The clothes-line hanger which is illustrated in the accompanying engraving is adapted to support a number of clothes lines at the same time, and yet permits of taking up the slack of the lines individually or altogether when desired The lines are attached at one end to a fixed support, while the other ends are connected to separate reels, all of which are mounted on a single shaft that may be wound up to stretch the lines taut. The shaft, which is indicated at *A*, is provided at intervals with square sections adapted to fit the square bores of the reels *B* The shaft is mounted in suitable brackets attached to a wall, and at each end is provided with a ratchet and a crank, so that it may be wound up to tighten the lines. Each line is provided with a hook at one end adapted to engage a corresponding eye in the bar *E*, which is made fast to an opposite wall or other support. Whenever it is desired to take in one of the lines, or to tighten it or loosen it with respect to the others, the reel on which it is wound is moved axially until it clears the squared section of the shaft *A*, and is then free to be turned in either direction Whenever desired, the bar *E* may be released from its support and the lines wound up A cover piece *D* may then be dropped over the reels to protect them from the weather A patent on this clothes-line hanger has been obtained by Mr George T. Van Riper, 152 South Ocean Avenue, Freeport, N Y



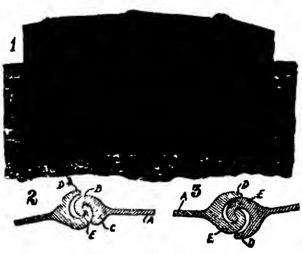
CLOTHES-LINE HANGER.



A NOVEL METHOD OF COOPERING CASKS.

### ROLLED STEEL PILING.

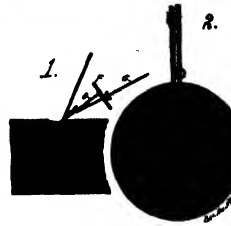
One of the defects of sheet steel piling as heretofore constructed is that the interlocking edges which connect one pile with another are apt to spread open when the piles are under strain. Pictured herewith is a new form of sheet piling with strong flexible joints, so constructed as to oppose spreading strains at the various positions which the piles may assume with relation to each other. Fig. 1 shows a set of piles driven in a curved row. Details of the interlocking parts are given in the sectional views, which show two different forms of piles. Each pile consists of a web *A*, furnished with a pair of flanges formed to interlock with the flanges of the next adjacent pile. In the construction shown in Fig. 2, the right and left-hand ends of the pile differ in design. The left-hand end has a wide tapering flange *B*, that is bent to the form of a hook, and a short, slightly curved flange *C*. The right end of the pile is somewhat similar in form, the flange *E* being curved to approximately the same form as flange *B*, but the flange *D* is considerably longer than the flange *C* Fig. 3 shows a preferred construction. The interlocking parts are of the same design, except that they are made in right and left-hand forms. With either design the interlocking flanges will rigidly be retained under pulling strains at whatever position the parts may assume. The piles are of simple construction, and may readily be rolled in rolls of proper design. The inventor of this piling is Mr William Neilson, of 1379 Montezuma Street, Pittsburg, Pa.



ROLLED STEEL PILING.

### GAS-MAIN STOPPER.

A novel form of gas-main stopper is illustrated in the accompanying engraving. It consists of a flexible diaphragm mounted on a collapsible spring frame, which may be expanded in the gas main by exerting pressure at two diametrically opposite points. The spring frame is indicated at *A* in the illustration, and when in collapsed condition is elliptical or oval in form. The diaphragm attached to the frame is shown at *B* Connecting opposite extremities of the oval shaped spring frame *A* are a pair of telescoping members *C*, to which the operating handles *D* and *E* are attached. It will be evident that when the handle *E* is drawn upward and handle *D* pressed downward, the member *C* will telescope, drawing the frame *A* into circular form In order to provide for operating both of the handle bars simultaneously, a crosshead *F* is fitted to the outer end of the bar *D*, and is provided with an aperture through which a threaded bar *G* is adapted to pass The bar *G* terminates in a hook, which engages a link secured to the bar *E*, and a thumb nut threaded on the bar *G* and bearing against the crosshead *F* serves to draw the bar *E* outward, and at the same time to press the bar *D* inward, so as to press the stopper into the circular form In use the stopper is introduced into the gas main through an opening, and inclined with its lower end extending toward the end from which the gas is flowing. The operating bars project through the opening, and when the thumb nut is tightened the frame is brought to a nearly vertical position, as indicated in the drawing, thus lying crosswise of the main and effectually stopping the flow of gas. The inventor of this improved gas-main stopper is Mr Patrick Goodman of 257 East 133rd Street, New York city



GAS-MAIN STOPPER.

### A NOVEL METHOD OF COOPERING CASKS.

It is customary to build casks with tapering sides, so that the hoops which bind the staves together may be jammed tightly in place. This makes it necessary to shape the staves, which entails considerable waste of material and much trouble in assembling and bending them into position. Another disadvantage is that the tapering or bulging cask requires more room for storage than if made truly cylindrical A novel method of overcoming these difficulties has recently been suggested. The accompanying engraving illustrates this method. Between the staves and the hoops rings are placed, which are tapered as indicated in the sectional view, Fig. 2. When the rings are driven down they act as wedges to jam the hoops tightly, so as to bind the staves in place. In order that the ring may contract in diameter as it is wedged into place, it is made of wire or a strip of metal that is crinkled or bent into a zigzag form. This lightens the construction, and provides a better grip on the hoops and staves. In many trades small kegs and casks of moderate size for liquids are required, but their high price and the cost of machinery for making them is prohibitive for many purposes. The casks here described are especially suited to meet the requirements of such trades, because after the staves and heads are prepared they can be finished inside and out (including cutting the grooves) in an ordinary lathe, producing an inexpensive cask of attractive and finished appearance. The inventor of this novel construction is Mr. William Houlker of Nelson, New Zealand.

### AREA-FINDING APPARATUS.

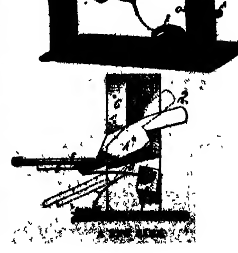
A very unique method of finding the area of surfaces with irregular boundaries is pictured in the accompanying engraving. It comprises a flat steel plate that is magnetized, and hence becomes a permanent magnet, and a number of soft iron balls. The size of the plate depends upon the dimensions of the area to be measured. The drawing on which the area is outlined is placed over the plate, and to protect the drawing a thin piece of paper is placed over it. The area outlined is then filled with the iron balls, which are flat on the under side to prevent them from rolling. The magnetized plate converts the balls into temporary magnets, causing them to cling to the plate and to each other. After the area of the drawing is filled, the balls are taken out and placed in a measuring frame, as indicated in the engraving, and the number of square inches occupied by the balls is ascertained. Tables are furnished which permit of reducing the square inches thus found to the scale of the drawing, thus giving the area sought without any calculation. It will be observed that the side members of the measuring frame are calibrated, and the sliding cross-bar is provided with vernier scales, so that the area occupied by the balls may be obtained with exactitude. The ease with which any given area can be set on first trial should make this apparatus valuable to engineers and surveyors. The apparatus is adaptable to irregular as well as regular surfaces. The inventor of the area finder is Mr Alfred C Freeman of Norfolk, Va.

AREA-FINDING APPARATUS.

### A NEW GAME.

Pictured in the accompanying engraving is a novel game apparatus, which is adapted to afford considerable recreation, as it calls for a certain amount of skill.

(*Concluded on page 19.*)



A NEW GAME.

## RECENTLY PATENTED INVENTIONS.

### Heating and Lighting.

MINER'S LAMP.—R. L. GRAVES, Sumpter, Ore. The present invention is an improvement on the two former patents granted to Mr Graves. In both the inventions covered by the above patents, the lamp is provided with means connected with the wick-tube, for heating and liquifying paraffin or other solid hydrocarbon, whereby it may be taken up by the wick and burned for illumination. In both, heat-conducting wires are used in connection with the wick proper, the same being extended alongside the wick and down into the body of the lamp

AUTOMATIC CUT-OFF FOR GAS-MAINS.—C. E. LAMMERS, New Philadelphia, Ohio. The invention refers to devices for preventing explosions or accidents caused by changes in the pressure in gas mains. An object is to provide a device which will automatically shut off the flow of gas from the mains when the pressure therein becomes too low, thereby preventing the accidents which might otherwise occur

DRILL-GUIDE.—A C NEAL, New York, N Y. The object of this improvement is to provide a device easily adjusted and inexpensive to manufacture. The invention relates to a device to be used to guide a drill in the twyere of a blast furnace when it is desired to remove the crusts or slag which have formed over the opening of the twyer. Mr Neal has invented another drill-guide, and his object is to prevent accidents to the drill-guide on back strokes of the drill. In other words, he provides a construction for holding the inner guide member loosely in position and in such a way that if struck by the head of the drill bit the blow will be cushioned.

SAFETY GAS CUT-OFF.—H TULLIS, Lisbon, Ohio. The aim in view in this case is to provide a mechanism for cutting off the supply of gas in the event of the same being inadvertently or otherwise temporarily suspended. A great deal of disaster and discomfort has been experienced in the past, due to the accidental or intentional suspension of gas service in buildings and renewal of the same after the light has become extinguished, due to suspension. To avoid this danger the mechanism has been invented.

LAMP.—HENRY SALSBURY, 124 Long Acre, London, England. The invention is especially applicable to lamps such as used in conjunction with motor vehicles. By providing suitable surfaces within the lens of the lamp, the rays of light which would be otherwise projected upward and produce glaring in the eyes of one approaching, are reflected downward and the beam of light emitted from the lamp restricted to a level below that of the line of vision of the observer. The glaring is especially noticeable in connection with acetylene lamps.

HOT-AIR FURNACE.—W MILLER, New York, N. Y. In the present patent the purpose of the inventor is the provision of a new and improved hot-air furnace, which is arranged to insure a rapid circulation and thorough heating of the air, and at the same time utilizing the burning fuel to the fullest advantage.

### Household Utilities.

CHAIR.—W P LAWRENCE, Colorado Springs, Colo. The invention has reference to certain improvements in metal chairs, the main object of the inventor being to construct a chair, the principal portions of which are formed of sheet metal, and all the parts of which are so connected together that all rivets, bolts or other fastening means are concealed from view

WASHING-MACHINE.—E. BARTHUN, Kewaskum, and C J GUTEKUNST, Campbellsport, Wis. The purpose here is to provide a washing-machine of the pounder type, which is simple and inexpensive and that may be operated by hand or other power, and which will rapidly and perfectly cleanse garments or other fabric that is operated upon by the machine.

ARM-CHAIR AND FOLDING BED.—J C. SMITH, Manchester, N H. The invention pertains to furniture, and the object is to produce a chair which can be readily converted into a bedstead. When the chair body is seated on the leg frame, the sides of the chair body fold over and around the foot section so that the latter operates to hold the chair in position.

ATTACHMENT FOR BEDS.—P H WILSON, Talent, Ore. The aim of the invention is to provide a bed having a stretcher disposed over the mattress with means for drawing the stretcher taut, a continuous belt having a surface disposed over the stretcher, the belt being disposed on drums at the head and foot of the bed respectively, there being means provided for rotating the drums.

### Machines and Mechanical Devices.

REVERSING MECHANISM FOR THE BAND-CYLINDERS OF SPINNING-MULES.—J. H. RYALLS, Charlottesville, Va. The improvement in this instance is in reversing mechanisms for band-cylinders of spinning-mules. In spinning, the warp is [illegible] in one direction, and the purpose of the present invention is to provide means for changing the direction of travel of the bands within a minimum of time. [illegible]

## Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 18th or will be sent by mail on request.

(12159) A. S says Suppose that a person riding in a passenger coach traveling at a high rate of speed in a straight line and tightly closed, so that there would be no air currents in it, could jump straight up a few feet and remain suspended in the air for a short time without touching any part of the coach, would he or would he not drift toward the back end of the coach? Also would a feather or other light article dropped from the ceiling of the coach fall perpendicularly, supposing the speed of the car to be constant in both cases? A Our usual reply to questions such as you propound is "Try it and see" Would not you be surprised, should you drop a book or a coin in a railway car, to have it rush away to the rear door? The fact is that all things in a car have the motion of the car at all times, and by inertia they preserve that motion even when dropped out of the car window, excepting for the resistance of the air Inside the car the air is traveling along with the car, when doors and windows are closed, as you suppose to be the case in your question Therefore a coin dropped in a rapidly moving car will not drift toward the rear of the car, but will fall to the floor as if the car were still.

(12160) J C says 1 Would ask you to please let me know if there is a way to attach paper to an electrified body like metal or something else which could be electrified, on the same principle as a bit of paper is attached to a body which is electrified by rubbing, or on the principle of the canceling machine employed in the post office at Washington, which draws the envelopes by an electrified belt and transmits them to be canceled in another part of the machine A Small pieces of paper will be drawn to an insulated piece of metal just as they are drawn to a belt or any other insulator which has been electrified by friction The reason a belt is electrified is that it is an insulator and is rubbed by its slip on the pulleys as it runs over them. 2. Also kindly inform me the name of the book and author announced in the SCIENTIFIC AMERICAN about six or eight weeks ago for the main instruction of the winding of electric magnets and dynamos The price of it was $1 50. I looked for it and could not find it again A. Perhaps the book for which you ask was Poole's "Designs of Small Dynamos and Motors," price $2. We cannot tell from your description, but we often refer inquirers to this book, and you will find it very clear and practical

(12161) W J says Can you tell me if there are any railroads now using iron ties instead of wood, and what are their names and addresses? Do these ties give satisfaction? If so, why do the railroads persist in using wooden ties? A. We regret that we have no recent statistics of the use of metal ties in this country, but they are very little used as yet They were condemned after trials extending over ten years by three leading railroads twenty years ago, but it is our impression that the failure was largely due to the roadbeds. In Europe, where the greater density of population and consequently of available capital per mile of railroads permits a perfection of roadbed only recently approached in this country, metal ties are in use which have been in place under favorable conditions for twenty-five and thirty years, their long life more than compensating for their higher first cost as compared with wood ties. Considering the rapidly increasing cost of the latter and the great improvement in permanent way on the best American railways in recent years, it is our opinion that a repetition of the trials would result in a reversal of the former decision on the score of economy

(12162) S A. D says Severe storms of thunder and lightning with snow and hail are of daily occurrence at La Fundicion, Peru, during the winter and spring. What is remarkable to me is the form in which the hail or frozen snow falls. This is almost always conical, with a convex base, the conical part being crystalline, in narrow converging prisms, and fairly translucent, the base is usually whitish and opaque. These cones will measure pretty regularly ¼ inch to 1-3 inch from base to point and transversely A The authorities agree in the theory that hail is formed in a whirling mass of air, which rotates in such a way that the forming hailstones are carried up and brought down perhaps several times before they become heavy enough to break through and fall to the earth. These motions produce the layers which can be seen in all hailstones, since in the cold regions the ice is firmer than in the warmer regions, where the temperature may not be much if any below the freezing point. The section of such a ball is necessarily somewhat circular Often the ball itself is egg-shaped. A conical form is more [illegible]. We cannot think of any reason why a conical form should be usual in a particular locality.

## NEW BOOKS, ETC.

HISTORICAL GUIDE TO THE CITY OF NEW YORK. Compiled by Frank Bergen Kelley. New York Ferderick A. Stokes Company, 1909. 16mo., 420 pp. Price, $1 50

This book was compiled from original observations and excursions made by members and friends of the City History Club of New York. It is illustrated by 46 engravings, and there are 70 maps of the utmost value. The historical guide to New York is the result of prolonged investigations of the city of New York to discover old landmarks and direct attention to the yet visible traces of the old town which lie hidden away and are fast disappearing from the city of to-day It is a complete guidebook to New York city and its environs, in the form of various excursions, carefully laid out, with full directions and maps. It describes buildings and landmarks now standing, and refers fully to historical events which have taken place either in them or on their sites. There are excursions to all points of the city, and special ones to museums and art galleries, by water by automobile, for children, etc. Such a guide is necessary for a knowledge of New York, either by citizen or tourist, since there is no other Eastern city where the traces of historical events have been so thoroughly effaced (except in outlying districts) although the region is peculiarly rich in history It is an admirable treatise

PATENTS AS A FACTOR IN MANUFACTURING By Edwin J Prindle. New York The Engineering Magazine, 1908. 16mo, 134 pp Price, $2.

The purpose of this volume is indicated by the author at the outset and emphasized at the conclusion as not in any sense to make the inventor or the manufacturer his own patent lawyer It is rather to convey an idea of the nature of a patent, the protection it may afford, the advantages it may possess for meeting certain commercial conditions the safety which may be secured in relations between employers and employees, and the general rules by which the courts will proceed in upholding the patent and in thwarting attempted infringements, and to show the manufacturer, in a general way, what may be accomplished by patents, but not to lead him to attempt such accomplishment without legal advice. Based on these eminently practical premises, the author proceeds to unfold his subject in a very lucid manner It is one of the best scientific discussions of patents as we find them to-day that we have ever seen

AMERICAN BUSINESS LAW With Legal Forms. By John J Sullivan, A.M., LL.B. New York D Appleton & Co., 1909 12mo, 433 pp Price, $1 50 net.

This book, while designed for use as a text book in the class room, is so written as also to be of practical value to business men throughout the country The statements of law are clear and terse, and many illustrative cases serve at once to explain and to brighten the text. A set of questions will be found at the end of each chapter, and a number of forms are introduced in appropriate places. The volume is divided into five books Book One concerns Contracts. Book Two relates to (1) Agency, (2) Partnerships, and (3) Corporations. Book Three treats of Bailments, Personal Property, and Real Estate. A chapter is devoted to the subject of Common Carriers. Book Four discusses Suretyship and Guaranty, and Insurance Book Five deals with the Estates of Decedents and Trust Estates.

DIRECT READING SLIDE RULE. With a Synopsis of Its Application to the Solution of Practical Problems. By George W Richardson. Chicago, Ill 4212 24th Place. 24mo., 25 pp Price, including celluloid and aluminium slide rule, $1 50.

This little work has been written as a guide rather than a treatise on the use of the slide rule. So much has been written on the subject that there is not much left to write about. Nevertheless, there is much to be learned about the practical application of this valuable instrument It has, therefore been the author's aim to deal with its practical application to the solving of the problems rather than to enter into any long-drawn-out, confusing statements as to the whys and wherefores in the case. What is wanted with the slide rule is results, and the author has certainly succeeded in producing one of the best direct-reading slide rules, and it is moreover sold at a price which places it in the reach of all draftsmen, and it is hoped that it may also reach business men as well. If they only realized the range of problems which this simple instrument can solve, the sales would be enormous. The rule before us will turn gallons into cubic inches, gallons into cubic feet, gallons into pounds of water, cubic feet into cubic inches, circumference vs. diameter circle, area vs. diameter circle side of a square vs. diagonal, kilowatts vs. horse-power B.T.U vs. horse-power evaporation from and at vs. boiler horse-power, direct radiation vs. size grate, diameter safety valve vs square feet grate, area vs. side of an equal square, cubic feet air per minute vs. area duct in square feet diameter steam main vs. square feet radiation, piston speed, feet per minute horse-power of engine, horse-power of a waterfall; belting vs. horse-power, how to square a number, how to find the square root of a number; how to cube a number; how to find the cube root of a number, etc.

CYRUS HALL MCCORMICK His Life and Work. By Herbert N Casson Chicago A. C McClurg & Co, 1909 12mo., 264 pp Price, $1 50 net.

The author states that whoever wishes to understand the making of the United States must read the life of Cyrus Hall McCormick. This is true as regards agricultural machinery, for no other one man so truly represented the dawn of the industrial era—the grapple of the pioneer with the crudities of a new country the replacing of muscle with machinery and the establishment of better ways and better times in farm and city alike Beginning exactly one hundred years ago, the life of McCormick spanned the heroic period of our industrial advancement, when great things were done by great individuals The author further truly states that he fed his country as truly as Washington created it and Lincoln preserved it He abolished our agricultural peasantry so effectively that we have had to import our muscle from foreign countries ever since The book is a most fascinating one and as it passes on from generation to generation, it may finally be polished into an Epic of the Wheat the tale of man's long wrestle with famine and how he won at last by creating a worldwide system for the production and distribution of bread.

THE SPATULA SODA WATER GUIDE. By E. F White. Boston Spatula Publishing Company Small 4to, 176 pp Price, $1

This is a complete compilation of valuable formulas and information for the manufacturer of carbonated waters and the dispensing of all kinds of carbonated drinks, the compounding of syrups, tinctures, extracts, fruit juices, etc, giving accurate instructions for the serving of each and every drink in the best and most attractive manner known Considering the enormous quantity of bad soda water with which the mass of people are served in large cities, it would seem that this book has a great field There is no good reason why quite elaborate drinks should not be dispensed at the ordinary fountains with the aid of such a complete compendium as the present volume Most of the formulae appeared originally in the Spatula, we notice that the author has recast many of them for this book, which hangs together very well and cannot be considered as a mere aggregation of formulas.

THE STANDARD GUIDE FOR LOCOMOTIVE ENGINEERS AND FIREMEN Also Railroad Machinists By Ed Turner Chicago Laird & Lee Vest pocket size Price, 75 cents.

## OXYGEN AND HUMAN ENERGY.

(*Concluded from page 4.*)

logical data. The air in our lungs is *complemental* (all that we can get into our lungs by forced inspiration); *tidal* (that which passes in and out in normal breathing), *reserve* (the air which can be expelled in forced expiration), and *residual* (which remains after forced expiration) Again, the pulmonary function is in obedience to the physical law of the diffusion of gases, by which a lighter gas (inspired air rich in oxygen) and a heavier gas (expired air laden with carbon dioxide) tend reciprocally to displace and replace each other From these physiological facts we comprehend that all the air inspired is not at the end of the given inspiration taken into the ultimate air vesicles, nor is all the vitiated air contained in these air vesicles expelled from them with a single expiration Thus, in any event, pure oxygen would never immediately reach its ultimate destination in the air vesicles, it would in fact get to them pretty much tempered, as in the normal. Nor is pure oxygen—so I would infer—ever supplied artificially for inhalation, if it were, it would probably not be respirable for any length of time, and would be positively injurious, if its use were persisted in

But now the use of pure, unmixed oxygen is being advocated for human beings who are in nowise ill, and there are circumstances in which such procedure might appear justifiable For example, Prof. W A. Anderson, a collaborator with Prof Chittenden of Yale, relates in the American Physical Education Review of May, 1909, in his article on "The Use of Oxygen in Mountain Climbing," that his party, leaving Mexico City, ascended Popo and Ixti, both of which mountains are above 17,000 feet high. Popo is the easier to climb, and was negotiated in the better weather, yet it presented the greater difficulties, and the party suffered much from mountain sickness and most distressing dyspnœa as the air became progressively rarefied On the other hand, when Ixti was negotiated, oxygen condensers were used, and by breathing this gas the top was triumphantly reached with but little of the distress that was experienced on Popo If these findings are corroborated, the one heretofore absolutely insurmountable difficulty in scaling the world's highest peaks should be eliminated, even Everest (24,000 feet) should be conquered, and almost any fair climber should be able to find that flag alleged to have been planted atop Mount McKinley

But other procedures are being advocated which do not appear to me so justifiable For example, Dr. Leonard Hill has been seeking to prove that oxygen is more sustaining than air, his experiments demonstrate that after the use of this gas one may hold the breath more than nine minutes I do not know what proportion of oxygen was used in the experiments, whether the gas was taken pure, or whether some compound of it was employed. The result stated is of course amazing, but it is not exceptional Trained and expert swimmers remain under water a number of minutes, when, of course, they have to hold their breath If memory serves me aright, I once saw a man in an exhibition remain in a tank under water twenty minutes. Dr Hill concludes that by taking oxygen before a quarter-mile race, an athlete should be able to hold his breath during the whole race, and devote the energy thus saved to faster running Somewhat more than a year ago, Dr Hill reported experiments he had made which he believed would lead to the breaking of athletic records, and his work was no doubt the incentive to like experiments since made in other scientific centers. Dr Hill's experiments led him to think that the panting and distress of athletes might be largely mitigated by breathing oxygen deeply before and after a race; the former to prevent distress and to increase running powers, the latter to relieve whatever distress occurs. At the London Hospital athletics oxygen was given to some of the runners immediately after the races, and greatly relieved their distress. A well-known athlete, Mr. Holding, ran an unpaced quarter of a mile in fifty seconds after breathing oxygen for three minutes; in the trial for the Olympian games he had been unable to do this in less than fifty-two seconds. It seems he was not more distressed than if he had run one hundred yards; there was, it was reported, a notable absence of that stiffness of the muscles and grogginess in the legs which follow great exertion in running. Another athlete, Mr Just, after breathing oxygen for three minutes, ran half a mile in one minute and fifty-five seconds, slightly beating his record.

I confess I am not much impressed by these achievements. I think, on the contrary, the preliminaries to them were reprehensible. Oxygen is a stimulant,* and it is for its stimulant properties that Dr. Hill advocates its use in athletics. This is especially bad for young men, who are generally our athletes. Youth should need no stimulants. We observe, moreover, the oxygen is given before a race, this is decidedly both unsafe and unphysiological. Human energy is thus increased, but the increase is abnormal, as is also the expenditure of energy. Nor are the sequels without disaster Do not our athletic young men, as it is, grow into maturity with bad enough hearts? Every doctor must give melancholy testimony that such is the case But here we are advised to stimulate unnaturally a heart already functioning to its limit. And it is unphysiological to give any stimulant before a feat of strength or a trial of endurance, capabilities are thus perversely and unnaturally overwrought. All stimulants—oxygen, whisky, coca, and the like—should be given not before, but after, a race, a journey, or a mountain climb, in order to restore the economy to par after the undue exertion. Here is a matter which seems to me not altogether trivial.

Besides, this "doping" of contestants before a race is unsportsmanlike. Tests of physical brawn and endurance are legitimate only when they are made under normal conditions—those in which human life must ordinarily be lived. The true sportsman will countenance athletics only when the contestant depends for success upon no other factors than his better physique and superior skill. Oxygen stimulation would possibly make an untrained, undeveloped, short-winded, soft-muscled specimen successful for the brief span of a given contest; but for all that he would be the poorer and not the better man. It may be recalled that some years ago a bicyclist "made" a mile in less than a minute, behind a railway train going at that rate; a smooth board course had been laid between the rails—and this was permissible enough But a shed had been built out from the rear of the last car, within which the rider kept. He was thus protected from the winds, especially headwinds, and was moreover assisted by the suction exerted by the fast-moving train. Genuine sportsmen rightly held his record to be valueless; for it was achieved under unnatural conditions, not under such as must be chanced and grappled with in nature.

* By stimulant is here meant an agent tending to excite organic action. The physiological stimulant ... [illegible]

## DAVID STARR JORDAN.

(*Continued from page 12.*)

of fishes, in the knowledge of which he now stands among the very foremost in this country. In 1879 he was elected to the professorship of biology in Butler University, which place he then held un-

(*Continued on page 17.*)

(Continued from page 16.)

(Continued from page 16.)
til 1872, when he was chosen to fill a similar chair in the University of Indiana, in the possession of which he continued until 1885, when he became president of that university

In 1885 Leland Stanford, who had served the State of California as its Governor and as its representative in the United States Senate, founded in memory of his son the Leland Stanford Junior University, having as its object to "qualify students for personal success and direct usefulness in life." This university with the richest foundation of any similar institution in the United States at that time, was formally opened on October 1st, 1891, with Dr Jordan as its president. Since that time he has continued to fill that important office, fulfilling with rare skill and unusual ability the will of its founder, who publicly said that "a generous education is the birth right of every man and woman in America."

Dr Jordan's great knowledge of fishes was early taken advantage of by the U S Bureau of Fisheries, and from 1877 until he went to Stanford University he served as assistant to the U S Fish Commission, as it was then called During 1896-98 he was a U S commissioner in charge of fur sealing investigations, and in 1904 was given charge of certain investigations in regard to the salmon for the government. In connection with his official researches he has made many trips on the Pacific, frequently visiting Alaska, Hawaii, and far-away Japan, making large collections, selections from which, especially types of new forms, have been deposited in the U S National Museum Of the publications of this institution, he prepared as "Contributions to North American Ichthyology," three bulletins entitled respectively I "Review of Rafinesque's Memoirs on North American Fishes" (1877), II A "Notes on Cottidæ, Etheostomidæ, Percidæ, Centrarchidæ, Aphododeridæ, Dorysomatidæ, and Cyprinidæ, with revisions of the genera and descriptions of new or little known species" B "Synopsis of the Siluridæ of the fresh waters of North America" (1877), and III A "On the distribution of the fishes of the Alleghany region of South Carolina, Georgia, and Tennessee, with descriptions of new or little known species" B "A Synopsis of the family Catostomidæ" (1878)

He has further enriched the many volumes of the Proceedings of the U S National Museum with accounts of his discoveries, which have gained for him the reputation of being the foremost authority on the sea fauna of the Pacific By far however, his greatest contribution to the Smithsonian publications is the well known Bulletin No 47, which he prepared in co-operation with Barton W Evermann It bears the title of "The Fishes of North and Middle America," and is essentially a descriptive catalogue of the species of fish like vertebrates found in the waters of North America, north of the Isthmus of Panama In it are described 225 families, 1,438 genera and subgenera, and 3,393 species and subspecies It forms four octavo volumes covering 3,313 pages with 392 plates, in which nearly 1,000 fishes are illustrated

Dr Jordan is also the author of "A Manual of Vertebrate Animals of Northern United States", "Animal Life", "Animal Forms", "Food and Game Fishes of North America", and "A Guide to the Study of Fishes." Several of these works were written in association with his scientific colleagues of the Bureau of Fishes and Stanford University.

His more popular contributions to literature include the following works in book form "Science Sketches", "Foot notes to Evolution", "Care and Culture of Men", "The Innumerable Company", "Imperial Democracy", "The Philosophy of Despair", "Voice of the Scholar", "The Call of the Twentieth Century", "The Human Harvest", "Evolution and Animal Life", and a single volume of

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO. Inc.

## BUSINESS OPPORTUNITIES

CAPITALIST wanted for U. S. Patent No. [illegible] aerial vessel. Plans from ready parachute; will not sink or upset. For further particulars address T. Seiler, [illegible] W[illegible] Avenue, Jersey City.

Inquiry No. 8918. For manufacturers of Wyatt's Electro Catalytic Sparking Plug.

## HELP WANTED

STEAM SHOVEL DESIGNER.—Wanted man with wide experience in their design and construction. Address stating experience Designer, Box 773 N. Y.

Inquiry No. 8990. For information regarding a substitute made of leather but similar to the same and are as durable.

## FOR SALE

FOR SALE.—Engine lathe, swings 8¼ in., takes 18 in. between centers. Complete with full set change gears to cut all size threads, 3 to 40 in. Price only $40.00. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 8997. Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power meters.

## TYPEWRITERS

REAL REMINGTON $18.75. One machine only in new localities to secure desirable agent. Special agents prices supplied on all makes of typewriters. 4 ribbons $1.0. Standard Typewriter Exchange, 23 Park Row, New York.

Inquiry No. 8996. Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

## MISCELLANEOUS.

HAIR GROWS when our Vacuum Cap is used a few minutes daily. Sent on 60 days free trial at our expense. No drugs or electricity. Stops falling hair. Cures dandruff. Postal brings illustrated booklet. Modern Vacuum Cap Co., 586 Barclay Block, Denver, Colo.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9016. Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9017. Wanted to buy silk machines from re-reeling, twisting, doubling to the final process of making it into clothes.

Inquiry No. 9025. Wanted address of rubber manufacturers of Germany.

Inquiry No. 9029. Wanted, data, prices and all information on machinery for braiding straw in manufacturing straw hats.

Inquiry No. 9031. For manufacturers of machinery that can drive lace stamps to kindling wood.

Inquiry No. 9036. Wanted the address of the manufacturers of Cycle Ball Bearing Suspenders.

Inquiry No. 9038. Wanted the address of the Chipman Electric Purifying Co.

Inquiry No. 9043. Wanted the address of Farney Safety Razor Co.

Inquiry No. 9044. Wanted to buy outfits necessary for agate polishing.

Inquiry No. 9046. Wanted machinery used for the manufacture of all kinds of fruit boxes, baskets and crates.

Inquiry No. 9048. Wanted address of manufacturers of metal table slides for extension tables.

Inquiry No. 9049. Wanted to buy rotary brushes suitable for a shoe shining machine.

Inquiry No. 9052. Wanted to buy machinery etc., for a beer plant, that manufactures beer by means of glucose.

Inquiry No. 9053.—Wanted address of firms who install plants to manufacture nitrogen.

Inquiry No. 9054. Wanted address of manufacturers of articles made from mica.

Inquiry No. 9055. Wanted address of parties interested in Log Cleaning Machines.

Inquiry No. 9056.—For manufacturers of window shades.

Inquiry No. 9057. For manufacturers of glass and china balls used as fixtures or ornaments on lightning rod equipment, also weather vanes for same purpose.

Inquiry No. 9058. Wanted firms who make machinery used for pulverizing soap-stone.

Inquiry No. 9059.—For manufacturers of flexible steel [illegible] mail.

## How to Construct An Independent Interrupter

In SCIENTIFIC AMERICAN SUPPLEMENT 1615 A. Frederick Collins describes fully and clearly with the help of good drawings how an independent multiple interrupter may be constructed for a large induction coil.

This article should be read in connection with Mr. Collins' article in SCIENTIFIC AMERICAN SUPPLEMENT 1605, "How to Construct a 100-Mile Wireless Telegraph Outfit."

Each Supplement costs 10 cents; 20 cents for the two. Order from your newsdealer or from

# Practical and Instructive Scientific Books

AGRICULTURE.—The New Agriculture. By T. Byard Collins. 12mo., 374 pages, 106 illustrations $2.00

A popular outline of the many changes which are revolutionizing the methods of farming and the habits of farm life. It is one of the most practical treatises on the subject which has ever been issued.

ALCOHOL.—Industrial Alcohol. Its Manufacture and Uses. By John K. Brachvogel. 8vo. 528 pages. 107 illustrations $4.00

A practical treatise based on Dr. Max Maercker's "Introduction to Distillation" as revised by Drs. Delbrück and Lange comprising raw material, malting and yeast preparation, fermentation, distillation, rectification and purification of alcohol, alcoholometry, the value and significance of a tax-free alcohol, methods of denaturing, its utilization for light, heat and power production, a statistical review and the United States law.

AMATEUR MECHANICS.—Home Mechanics for Amateurs. By George M. Hopkins. 12mo. 370 pages. 326 illustrations $1.50

This is a thoroughly practical book by the most noted amateur experimenter in America. It appeals to the boy as well as the more mature amateur. Holidays and evenings can be profitably occupied by making useful articles for the home or in the building of small engines or motors or scientific instruments.

AMUSEMENTS.—The Scientific American Boy. By A. Russell Bond. 12mo. 317 pages. 340 illustrations $2.00

This is a story of outdoor boy life suggesting a large number of diversions which, aside from affording entertainment, will stimulate in boys the creative spirit. In each instance complete practical instructions are given for building the various articles.

COMPRESSED AIR.—Compressed Air. Its Production, Uses and Application. By Gardner D. Hiscox. 8vo. 665 pages. 540 illustrations $5.00

The most complete book on this subject. It treats on its physical and operative properties, and is written by an expert. Taken as a whole it might be called an encyclopedia of compressed air.

DIES.—Their Construction and Use for the Modern Working of Sheet Metals. By Joseph V. Woodworth. 8vo. 384 pages. 505 illustrations $3.00

A most useful book, and one which should be in the hands of all engaged in the press working of metals, treating on the designing, constructing and use of tools, fixtures and devices, together with the manner in which they should be used in the power press, for the cheap and rapid production of sheet metal articles.

ELECTRICITY.—The Standard Handbook for Electrical Engineers. Written and compiled by a Staff of Specialists. Second edition, corrected. 12mo. 1285 pages. 1260 illustrations. Bound in flexible morocco $4.00

A new pocketbook consisting of twenty sections, each written by a specialist of engineering experience and containing the latest data and information regarding standard electrical practice.

ELECTRICITY.—Electrician's Handy Book. By T. O'Conor Sloane. 761 pages. 556 illustrations. Handsomely bound in red leather pocket book style $3.50

This work is intended for the practising electrician who has to make things go. Although the principles of electricity and magnetism are treated, the greater part of the book is devoted to practical handling of machinery, details of construction and computations such as will be encountered in every day practice.

GAS ENGINES.—Modern Gas Engines and Producer Gas Plants. By R. E. Mathot. 8vo. 314 pages. 152 illustrations $2.50

A practical treatise setting forth the principles of gas engines and producer design, the selection and installation of an engine, conditions of perfect operation, producer gas engines and their possibilities, the care of gas engines and producer gas plants, with a chapter on volatile hydrocarbon and oil engines.

GAS ENGINES.—Gas, Gasoline and Oil Engines. Including Producer Gas Plants. By Gardner D. Hiscox. 8vo. 478 pages. 418 illustrations $2.50

A complete book on the subject for gas engine owners, gas engineers and intending purchasers of gas engines, treating fully on the construction, installation, operation and maintenance of gas, gasoline, kerosene and crude petroleum engines, with special information on producer and suction gases.

GAS ENGINES.—Gas Engine Construction. By H. V. A. Parsell and A. J. Weed. 8vo. 304 pages. 145 illustrations $2.50

A practical treatise describing the theory and principles of the action of gas engines of various types and the design and construction of a half horse-power gas engine, with illustrations of the work in actual progress, together with the dimensioned working drawings giving clearly the sizes of the various details.

HEATING.—Practical Steam and Hot Water Heating and Ventilation. By Alfred G. King. 8vo. 402 pages. 304 illustrations $3.00

An original and exhaustive treatise prepared for the use of all engaged in the business of steam, hot water heating and ventilation. The standard and latest book published. Describes all of the principal systems of steam, hot water, vacuum, vapor and vacuum vapor heating, together with the new accelerated systems of hot water circulation, including chapters on up-to-date methods of ventilation.

HYDRAULICS.—Hydraulic Engineering. By Gardner D. Hiscox. 8vo. 315 pages. 305 illustrations $4.00

A practical work treating on the production, power and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits, the horse-power of falling water, turbine and impact water wheels, wave motors, centrifugal, reciprocating and air-lift pumps, etc.

INDUCTION COILS.—The Design and Construction of Induction Coils. By A. Frederick Collins. 8vo. 295 pages. 160 illustrations $3.00

This work gives in minute details full practical directions for making eight different sizes of coils, varying from a small one giving a ½-inch spark to a large one giving 12-inch sparks. The dimensions of each and every part down to the smallest screw are given, and the descriptions are written in language easily comprehended.

LATHES.—Modern American Lathe Practice. By Oscar E. Perrigo. 8vo. 424 pages. 314 illustrations $2.50

A new book describing and illustrating the very latest practice in lathe and boring mill operations, as well as the construction of and latest developments in the manufacture of these important classes of machine tools.

MAGIC.—Magic, Stage Illusions, and Scientific Diversions, Including Trick Photography. Compiled and edited by Albert A. Hopkins. 8vo. 568 pages. 420 illustrations $2.50

This very interesting volume is acknowledged to be the standard work on magic. It appeals to the professional and amateur alike. The illusions are all explained in detail, showing exactly how the tricks are performed.

MECHANICAL MOVEMENTS.—Mechanical Movements, Powers, and Devices. By Gardner D. Hiscox. 8vo. 400 pages. 1,800 illustrations $2.50

This is a collection of different mechanical motions and appliances, accompanied by appropriate text, making it a book of great value to the inventor, the draftsman and to all readers with mechanical tastes.

MECHANICAL APPLIANCES.—Mechanical Appliances, Mechanical Movements and Novelties of Construction. By Gardner D. Hiscox. 8vo. 396 pages; 990 illustrations $2.50

This book, while complete in itself, is in fact a continuation of the author's "Mechanical Movements, Powers and Devices." The author presents to the reader information regarding nearly all conceivable devices for producing motion or accomplishing mechanical results.

SPECIAL OFFER: These two volumes sell for $2.50 each, but when they are ordered at one time from us, we send them prepaid to any address in the world on receipt of $4.

PATENTS.—Practical Pointers for Patentees. By F. A. Cresee. 12mo. 144 pages $1.00

Containing valuable information and advice on the sale of patents and elucidation of the best methods employed by the most successful inventors in handling their inventions. It gives exactly that information and advice about handling patents that should be possessed by every inventor who would achieve success.

PHYSICS.—Experimental Science. Elementary, Practical and Experimental Physics. By George M. Hopkins. In two volumes. 8vo. 1,105 pages. 918 illustrations. Cloth $5.00. Half morocco $7.00

This book treats on the various topics of physics in a popular way and describes with rare clearness and in detail the apparatus used, and explains the experiments in full, so that teachers, students, and others interested in physics may readily make the apparatus without great expense and perform the experiments without difficulty.

PLUMBING.—Modern Plumbing Illustrated. By R. M. Starbuck. 392 pages. 10¼ x 7¾. 55 full page engravings $4.00

A comprehensive and up-to-date work illustrating and describing the drainage and ventilation of dwellings, apartments and public buildings, etc. The very latest and most approved methods in all branches of sanitary installation are given.

PUNCHES.—Punches, Dies, and Tools for Manufacturing in Presses. By Joseph V. Woodworth. 8vo. 482 pages. 702 illustrations $4.00

This work is a companion volume to the author's other work entitled "Dies, Their Construction and Use." It might well be termed an encyclopedia on die making, punch making, die sinking and sheet metal working.

RECEIPTS.—The Scientific American Cyclopedia of Receipts, Notes and Queries. Edited by Albert A. Hopkins. Containing 15,000 selected formulas. 8vo. 734 pages. Cloth $5.00. Sheep $6.00. Half morocco $6.50

Over 15,000 selected receipts are here collected, nearly every branch of the useful arts being represented. The alphabetical arrangement with abundant cross references makes it an easy work to consult. It has been used with equal success by chemists, technologists and those unfamiliar with the arts, and is a book which is useful in the laboratory, factory or home.

REFERENCE BOOK.—Scientific American Reference Book. Compiled by Albert A. Hopkins and A. Russell Bond. Containing 50,000 facts. 12mo. 516 pages, illustrated $1.50

This book deals with matters of interest to everybody. It contains 50,000 facts and is much more complete and more exhaustive than anything of the kind which has ever been attempted. It is indispensable to every family and business man. It is a book for every-day reference—more useful than an encyclopedia because you will find what you want in an instant in a more condensed form.

STEAM ENGINES.—Modern Steam Engineering in Theory and Practice. By Gardner D. Hiscox. 8vo. 487 pages. 405 illustrations $3.00

This is a complete and practical work issued for stationary engineers and firemen dealing with the care and management of boilers, engines, pumps, superheated steam, refrigerating machinery, dynamos, motors, elevators, air compressors and all other branches with which the modern engineer must be familiar.

TELEPHONES.—Telephone Construction, Installation, Wiring, Operation, and Maintenance. By W. H. Radcliffe and H. C. Cushing, Jr. 16mo. 171 pages. 125 illustrations $1.00

A practical book intended for electricians, wiremen, engineers, contractors, architects, and others interested in the installation of telephone exchanges in accordance with standard practice. Intricate mathematics are avoided and all apparatus, circuits, and systems are thoroughly described. Wiring tables, which are very helpful, are also included.

TOOLS.—American Tool Making and Interchangeable Manufacturing. By Joseph V. Woodworth. 8vo. 535 pages. 601 illustrations $4.00

A complete practical treatise containing a valuable collection of drawings and descriptions of devices, the results of the author's own experience.

TOOLS.—Modern Machine Shop Tools. By W. H. Vandervoort. 8vo. 552 pages. 673 illustrations $4.00

A new and fully illustrated work describing in every detail the construction, operation, and manipulation of both hand and machine tools, being a work of practical instruction in all classes of machine shop practice.

WIRING.—Electric Wiring, Diagrams and Switchboards. By Newton Harrison. 12mo. 272 pages. 105 illustrations $1.50

This work is a thoroughly practical treatise on [illegible]

Any of the above books will be sent prepaid on receipt of price.

Our complete catalogue of scientific and technical books sent free on application.

verse entitled "To Barbara." Many of these books are collections of his lectures and addresses before popular audiences, for Dr Jordan has always been in demand as a speaker from the lecture platform.

Many honors have come to him. The degree of M D was conferred on him by the Indiana Medical College in 1875, that of Ph.D was given him by Butler University in 1878, while that of LL D was conferred on him by his alma mater in 1886, and by the Johns Hopkins University in 1902. He is a member of many scientific societies, including the American Philosophical Society, and during 1896-8 he was president of the California Academy of Sciences. Besides the foregoing he is a vice president of the Carnegie Foundation for the Advancement of Teaching.

The American Association for the Advancement of Science enrolled his name among its members at its second Montreal meeting in 1882, and a year later he was advanced to the grade of Fellow. The section on Biology made him its vice-president for the year 1895, but absence from the country prevented him from accepting the office on that occasion. Accordingly in 1900 he was again chosen, and presided over the section at the Denver meeting, delivering a retiring address on "The Fish Fauna of Japan with Observations on the Geographical Distribution of Fishes." At the meeting held in Baltimore a year ago this time Dr. Jordan was the unanimous choice of his scientific associates for the highest office in the gift of the Association, and will take the chair at the Boston meeting.

## A NEW GAME

(Concluded from page 11.)

It consists in general of a peg provided with a set of recesses which are numbered 5 10 15, etc. and a projecting device adapted to throw a ring on this peg, so that it will hang from any one of these recesses. The projecting device casts the ring in such a way that it turns a complete somersault in transit, which adds to the difficulty of making the ring fall in the recess bearing the highest number. The projecting device is shown in detail in cross-sectional view. It consists of a lever $A$ provided at its lower end with a flat plate $B$ adapted to receive the projectile. The lever $A$ is mounted between a pair of uprights $C$ and a spring $D$ presses the lever upward against a stop piece. The ring $E$ is placed on the plate $B$ and then the lever is raised as indicated by the dotted lines, and on being suddenly released throws the ring to the peg $F$. The recesses above referred to are indicated at $G$. It will be evident that considerable skill is required to gage the exact height to which the lever $A$ must be lifted, so that when released it will throw the ring to the desired recess. To assist in operating the projector the top crosspiece of the frame $C$ projects at each side, and provides a rest for the fingers while the thumb is engaging the end of the lever $A$. The inventor of this game is Mr Pierre V Ericson, Cherokee Avenue, Hollis, Long Island, N Y.

In a recent number of the Zeitschrift Phys. Chem., T Svedberg describes some experiments on the limit of visibility of color produced by various substances in dilute solutions passing from copper sulphate to fuchsine and colloidal gold. It is shown that in the case of colloidal particles the absorptive power is at first almost independent of the size, but proportional to the number, of the particles. On reducing the size of the particles, however, their absorptive power becomes less and finally the ordinary condition of a transparent (true) solution is attained. Svedberg argues that his experiments demonstrate the continuity of the colloidal and crystalloid states, and therefore the corporeal existence of molecules.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## A NEW ERA OF THE STEAM ENGINE.

If in the days of the perfected quadruple-expansion steam engine, anyone had ventured to criticise the type as being very inefficient as a means of extracting the heat energy of the steam that passed through it, he would have been considered as hypercritical, to say the least. And if he had ventured to predict that within a few years, by interposing a certain device between the low-pressure cylinder and the condenser, it would become possible to show an increased economy of from 25 to 35 per cent, and, in some cases, to increase the total horse-power output of an engine by from 70 to 100 per cent, he would have been regarded as a visionary. Yet it is a fact that this doubling of the capacity of an engine has actually been accomplished, as stated in our editorial of December 18th, 1909, describing the remarkable work being done at the Fifty-ninth Street power station of the New York subway system.

It is no exaggeration to state that the low-pressure turbine has introduced an era of improvement in steam-engine practice which is destined to mark an advance in the art, greater than any recorded during the past century of the history of this great prime mover, and we say this with full appreciation of the progress that was made with the introduction of compounding and the later multiple-expansion engines.

A century ago, as we recently showed in our discussion of the low-pressure condensing engines of the time of Robert Fulton, boilers were so weak and steam pressures so low that the condenser was an absolutely necessary accessory. When iron and steel plates became available for boiler manufacture, there was a corresponding rise in steam pressure, which led to a gradual abandonment of the condenser and a tendency to obtain the desired horse-power by working on the higher ranges of pressure. The high-pressure engine exhausting directly to the atmosphere was, of course, an extremely wasteful device, and the invention of the compound engine was logical and inevitable. Then followed the triple and quadruple engines, the limit of expansion being reached when the low-pressure cylinder became too large for practical purposes. If a cylinder were built that would carry the expansion of the steam down to the full theoretical limit of reciprocating-engine efficiency, its dimensions would be exaggerated out of all proportion to the rest of the engine; the weight would be enormous, and the losses through friction, and because of the great radiating surface, would be prohibitive.

The steam turbine, on the other hand, is particularly adapted for accommodating the great expansion of the steam in the lower ranges of pressure, just as the reciprocating engine is better suited for developing the expansion in the higher ranges. The turbine losses in the higher ranges are largely due to the friction of the rapidly revolving blades in the steam at its relatively high density when under high pressure, whereas skin friction is not a serious factor during the expansion of steam in a high-pressure cylinder. At the lower pressures the steam has a small density, and the skin friction losses are inconsiderable. Again, the great drop in temperature in a low-pressure cylinder induces rapid condensation, and greatly reduces the efficiency.

Hence, it will be seen that the reciprocating engine working on the higher ranges of pressure and the turbine working on the lower ranges are the complements, the one of the other, and when acting in combination form an ideally economical arrangement.

The range of application of the new system is wide, and already the turbine is winning back for useful work an enormous amount of heat which was formerly lost in the reversing rolling engines at the steel works, in the winding engines of collieries, and in the power houses of various industrial establishments, where it has become possible to run an addition to the [illegible] on the power recovered between cylinder and condenser. The largest steamships in the world, now under construction, will embody the same combination in their engine rooms. In these days of anxiety over the rapid depletion of our natural resources, the auxiliary steam turbine must be welcomed as one of the greatest conservers of our supplies of coal and liquid fuel.

## RAPID TRANSIT BY BELT CONVEYER.

By the action of the Board of Estimate of this city, which, on December 3rd last, passed a resolution authorizing the Public Service Commission to lay out a moving platform subway in Thirty-fourth Street between Second and Ninth Avenues, there will be given an opportunity to test a system of transportation which we have always considered to be ideally adapted for relieving the crowded traffic conditions in congested centers of large cities.

By far the most efficient means of moving material in bulk is the belt conveyer. For transporting material that is in a more or less finely divided condition, or made up of a large number of small separate units, such material, for instance, as grain, coal, or iron ore, the belt conveyer is recognized in the industrial world as having no equal—provided, of course, that the distance to which the material is to be carried and the speed are not excessive.

The moving platform is practically a continuous belt conveyer for the conveyance of a large number of passengers at moderate speed. It consists of short lengths of platform, coupled together, forming an endless chain which is kept in continuous motion. In the Thirty-fourth Street subway there will be four parallel rows of platform, the first, adjoining the station platform, moving at three miles an hour, the next at six miles, the third at nine miles, while the fourth, which will be entirely covered from end to end with seats, will move continuously at twelve miles an hour. Entrances to the moving-platform subway will be placed at every intersecting avenue or street, as the case may be. The capacity will be 73,500 seated passengers per hour in one direction during the rush hour, as against 13,000 seated passengers on the eight-car express train service and 7,500 on the five-car local train service of the subway, and as against 36,000 standing and seated passengers per hour on the express service and 22,500 on the local service.

In a recent communication to the Public Service Commission by its chief engineer, Henry B. Seaman, the advantages of the new system are stated to be: First, a vastly increased capacity and seats for all passengers, second, absence of the delay incurred by waiting for trains at stations since the train is always there and constantly moving; third, the fact that passengers may board or leave the train at any point at will, and that instead of placing stations one-third of a mile apart, as on the present subway, they may be placed at every cross street, or indeed at any intermediate point. Furthermore, the subway construction may take the form of a continuous arcade, thus providing an additional business front for display and shopping purposes.

Although the moving platform speed of twelve miles per hour may seem somewhat slow as compared with the running speed of a subway train, the difference is not nearly so great as might be supposed, and, indeed, over the shorter distances, is entirely in favor of the new system. The Commission's engineer finds that for all distances of less than four miles the moving platform is a quicker and more convenient mode of conveyance than the local train service, or even quicker than the local and express service combined, a passenger reaching Times Square Station, Forty-second Street, from any local station south of Fourteenth Street quicker by the moving platform than by the local and express trains of the present subway. The local trains ordinarily average, including stops, about fifteen miles per hour, and twelve miles an hour during the rush of traffic. If this rush hour service is compared with a platform speed of twelve miles the platform will have the advantage for all distances, because there is no train interval to wait and no distance between stations to walk.

To our mind the principal difficulty with such a system will be in accustoming passengers to step from one surface to another that is moving three miles an hour faster. Were it not for the great advantage of ample seating accommodation, easy accessibility, and total absence of waiting, to say nothing of the avoidance of the present abominable crowding, one might anticipate some reluctance on the part of the public to make use of so novel a means of conveyance. Experience with escalators, however, would indicate that the public will quickly become familiar with the motion of the platforms. If the new Thirty-fourth Street venture fulfills its promise, it will mark a new era in the history of [illegible].

S[illegible] English railroads to [illegible] electric traction to those which [illegible] much attention recently in this country. [illegible] these are the Mersey Railway, [illegible] the North-Eastern and the Midland, and a section of the London, Brighton and South Coast. Some of these roads have now been sufficiently long under electric operation to afford data for reliable comparison of the relative economies and advantages of operation by steam and by electricity, and the facts which were given at a recent meeting of the Institution of Civil Engineers prove that the adoption of electric traction has been abundantly justified. A comparison of three years' operation of the Mersey Railway under both methods shows that the locomotive and car expenses have been considerably reduced. Furthermore, under steam traction one pound of coal costing sixteen shillings per ton moved one ton 2.21 miles at an average speed of 17¾ miles per hour, whereas under electric traction one pound of coal costing eight shillings and nine pence per ton moved one ton 2.29 miles at an average speed of 22¼ miles per hour. The cost of maintaining the track and roadbed has been reduced from 0.0308 of a penny to 0.0089 of a penny per mile. Under steam traction the rails required renewal after carrying 22 million tons, under electric traction their capacity is 47¼ million tons. Furthermore, electrification has raised the average speed on the Mersey Railway, including stops, from 15.6 to 19.9 miles per hour, the number of ton-miles per annum has gone up from 43 to 67 million, and the total expenses per ton-mile, even with the interest on capital cost of the electric installation reckoned in, have been reduced from 0.344 to 0.293 of a penny.

On those branches of the North-Eastern Railway that have been electrified, the train mileage has been doubled, the platform capacity of the main station at Newcastle has been increased, and the number of signal movements has been reduced by one-half. These advantages, coupled with the higher rate of acceleration of the electric trains, have enabled these roads to carry a traffic that would have completely swamped the old steam service.

It is of interest to note that in connection with the electrification of a branch of the Midland Railway, tests which are being made of the relative advantages of direct-current and single-phase operation seem to show that not only is the single phase taking care of the same service as the direct current, but that the weight of the trains is only slightly greater, and the consumption of energy somewhat less. It is to be hoped that our New York Central and New Haven systems, which are operated respectively by the direct and the alternating current, will make public, for purposes of comparison upon a common basis, the results of the past two years of electric operation. If these figures were given, together with the cost of steam operation of these same sections of road, the electrical world would be furnished with a mass of data of exceptional value and interest.

## PRIZES AT THE LOS ANGELES AVIATION MEETING.

The prizes that are to be competed for by heavier-than-air machines at Los Angeles (January 10th to 20th) are the following:

$10,000 for the machine which, carrying two or more persons, breaks all world's records for duration, altitude, distance, and speed.

$7,500 for the machine making the best general average in all events. $5,000 for the machine which breaks all previous records and makes fastest circuit of the course. $5,000 for breaking height record. $5,000 for breaking endurance record.

$500 each for the circuit of least diameter; leaving the ground in the shortest time; shortest distance required in starting; greatest ability during flight (general average); longest glide with motor shut off; best general average in landing at given point. A prize of $1,500 for a machine designed and built by a resident of California, Arizona, or Nevada which flies 5 miles, and one of $500 if a flight of over 2 miles is made. $500 for a machine designed and built in California which flies at least 1 mile. A prize of $1,000 is also offered for a machine that [illegible] (glider) without power save that of [illegible].

A prize of $10,000 [illegible] for the dirigible balloon which [illegible] [illegible]

## ENGINEERING.

There has recently been launched at Bath, Me., the largest wooden vessel ever built in the United States. The "Wyoming," as she has been named, is a six masted schooner of 3,730 gross tons, with a total length over all of 350 feet. Next to her in size among wooden vessels is the "William L. Douglas," with a gross tonnage of 3,708.

The launch of the battleship "Utah" at the yards of the New York Ship Building Company, Camden, N. J., signalizes, for the time being, the possession by the United States navy of the largest battleship afloat. Both this ship and the "Florida," now being built at the Brooklyn navy yard, are of 21,825 tons displacement, and each will carry ten 12-inch guns.

Toward the close of last year the four-mile tunnel through the Andes on the line of the new transandine railway between Chili and Argentine was broken through. The tunnel lies on the Chilian side of the boundary line between the two countries and forms the summit of a new single-track road. It is expected that the tunnel will be completed and the whole line opened in the spring of the present year.

In his annual report to the Secretary of War, Gen. Murray, Chief of the Coast Artillery, announced that the difficult problem of mining the waters of the "race" at the eastern entrance to Long Island Sound has at last been solved. By using anchors of 1,500 pounds weight mines were successfully anchored at the great depth of 200 feet. A complete submarine equipment for the "race" will soon have been put in place.

The British Congo section of the Cape-to-Cairo Railway, 134 miles in length, was formally opened on December 12th. It extends from the Chartered Company's terminus at Broken Hill to the southern frontier of the Congo Independent State. This completes a continuous British line of 2,147 miles north from Cape Town. Work is in progress on an additional 160 miles, which will probably be completed in the autumn of 1910.

The "Vanguard" of the British navy, which has now undergone her trials with a maximum high-power speed of a fraction under 22 knots, is the fourth dreadnought to be completed for the British navy. Her displacement is 19,250 tons. She carries ten 12-inch guns disposed similarly to those of the original Dreadnought, that is, with six on the center line and two on either broadside. On the full-power trial the coal consumption per shaft horse-power was 1.68 pounds, and the main steam consumption was less than 14 pounds per shaft horse-power per hour.

The United States Engineer Corps are engaged in surveying the route of the proposed Atlantic Coast Canal from Boston, Mass., to Key West, Fla. The scheme calls for a canal from Boston to the coast through Long Island Sound to and across New York Bay, thence across New Jersey to the Delaware River, thence to Norfolk on Chesapeake Bay, and thence to the sounds of North Carolina and Beaufort Inlet. The law providing for this survey calls for surveys for a 25-foot ship canal from Boston to Beaufort and a 12-foot canal from Beaufort to Key West. The estimated cost is $100,000,000.

To facilitate traffic across the huge Culebra cut, and to carry certain air and water mains, a highway suspension bridge with a span of 600 feet has been built across the cut at Empire. Most of the material for the bridge was found on hand at Panama. The stiffening truss was made up of 4 x 6 and 6 x 6 timber, and the towers were built up of 6 x 12 and 5 x 10 creosoted pine timber bolted up in 16-foot lengths. The main cables, 870 feet in length, are 2¾ inches in diameter and have each a tensile strength of 170,000 pounds to the square inch.

The managements of several railroads have followed the lead of James J. Hill in impressing upon the farmers the need for conservation of the fertility of the soil, and they are using for this purpose the demonstration train. One of the latest of these, equipped by the Pennsylvania State College, is being operated on a division of the Pennsylvania lines, and other instruction cars are following a route through Iowa and Nebraska. The return to the railroads for the outlay for this enterprise will consist in the increased amount of freight brought to their lines as the result of more intelligent farming.

The introduction of the articulated compound type has made it possible for the railroads to greatly increase the effectiveness of existing locomotives which have become unequal to the work demanded. The Baldwin Locomotive Works have recently enlarged a consolidation engine for the Great Northern Railway by extending the boiler shell to include a superheater and feed-water heater, and placing beneath the extension a separate low-pressure six-coupled engine. It is estimated that the coal consumption per ton mile will be reduced by nearly [illegible] per cent, 10 per cent being due to superheating, 15 per cent to feed-water heating, and [illegible] per cent to compounding.

## ELECTRICITY.

The Nobel prize for physics has been divided this year, one-half being given to Guglielmo Marconi for his development of wireless telegraphy and the other half to Prof. F. K. Braun of Strasburg University, Germany, for his work in radio-activity.

Experiments are under way to establish wireless telegraph communication between Japan and San Francisco by way of Hawaii. Also to telegraph direct from Japan to San Francisco. So far these efforts have been unsuccessful, although telegrams have been received in Japan from Hawaii. However, the transmission was too uncertain to be of any commercial value.

The scout cruisers "Birmingham" and "Salem" were sent recently on a cruise to test the efficiency of their wireless telegraph system and that of the station at Brant Rock, Mass. The cruisers were to attempt to maintain communication with each other over a distance of a thousand miles, and with the land station over a distance of three thousand miles. Owing to severe storms the test was not very successful. Doubtless further tests soon will be undertaken under more favorable conditions.

A new steam-electric locomotive is being built in England. It comprises a steam turbine which operates a dynamo supplying current for four series-wound motors. The engine is being designed to haul express trains, and will be tested in actual service so as to show its efficiency as compared with the ordinary steam locomotive. It is pointed out that turbo generators have proved so efficient in stationary plants that a similar system would very probably prove to be of value on railways to replace steam locomotives.

A writer in Engineering (London) calls attention to the water power of Iceland, which is going to waste. A company is now being formed to exploit these power resources. The Skjálfandi River Falls comprise the Goda Falls with 29,200 horse-power, the Aldeyjar Falls with 35,800 horse-power, the Barma Falls with 17,000 horse-power. The Laxau River Falls would produce 30,000 horse-power, the Sog Falls 50,000 to 70,000 horse-power, and the Guldfoss Falls 100,000 horse-power. With all this hydraulic power available Iceland would seem to be an ideal spot for the generation of electricity, particularly for use in electro-chemical industries.

A press report from England speaks of a remarkable development in wireless telephony which will make it possible within a few weeks to carry on conversation between Paris and New York. As the record distance over which wireless telephonic conversation has been held even under the most favorable conditions is but a hundred miles or so, it is impossible to believe the press dispatch. It is very difficult to telegraph over so great a distance, and as the developments in wireless telephony are in their infancy and far short of those in wireless telegraphy, it is probable that we will have to wait many years before conversation can actually be maintained between the cities named.

A new type of car has been built for a line in Brunswick, Ga., in which the conductor is eliminated. The cars are of the "pay-as-you-enter" type, but may be entered only from the front platform, where the fare is deposited in the cash box under the motorman's eye. The cash box is provided with a glass receiver in which the fares may be examined before being dropped from the tilting bottom into a locked cash drawer. The cash box must be moved to the other platform when the car is on its return trip, and this has made it necessary to provide certain precautions to prevent coins from dropping out in case the box is turned upside down, and to lock the cash drawer when the box is removed from the support. The box is also provided with a fare-counting machine.

An interesting comparison of the New York and Paris subway systems was published in a recent number of the Electric Railway Journal. The following conclusions were reached: In the Paris system the average fare is but 2.7 cents, with a minimum fare of 1.19 cents at certain hours of the day. The Paris system offers universal transfers over a complicated network of lines, and when this network is completed a passenger may travel from any quarter of the city proper to any other quarter for a single fare. Our own system, on the other hand, charges a much higher fare, though the possible ride is longer. Allowing for difference in purchasing power of money, the charge per mile for the average ride is from one and one-half to two times as great in Paris as in New York. The lines extend into undeveloped areas fourteen miles from the center of traffic as against three or four miles in Paris, and a greater speed is attainable. The average speed in Paris is but twelve miles per hour, while in New York on the express tracks between the Brooklyn Bridge and 96th Street the rate is twenty-four miles an hour including stops, while the average speed for both express and local trains for the entire system is eighteen miles per hour.

## SCIENCE.

Former President Roosevelt's African hunting trip will result in enlarging the Smithsonian collection by 6,663 skins. The collection consists of hides of 243 large mammals, 1,500 small mammals and 1,356 stuffed birds. Human skulls picked up along the line of the ancient slave trail are also included.

Prof. Hergesell, Count von Zeppelin's mathematical and meteorological adviser, is now in New York. He states that two airships will be used by Count von Zeppelin with a view to exploring the entire region within the Arctic Circle. One will probably be left at a relief station in Spitzbergen, while the other is on its journeys, the two keeping in touch by means of wireless telegraphy. The German government will undoubtedly aid the undertaking financially.

Charcoal, graphite and diamonds are only different forms of one chemical element, carbon. Hitherto carbon has been regarded as infusible, but it has apparently been fused in experiments which were described by the Italian physicist La Rosa at the last International Congress of Applied Chemistry. By subjecting very pure sugar charcoal to the intense heat of the singing electric arc La Rosa obtained a compact mass of graphite. When this mass was cooled quickly minute transparent crystals appeared, which were proved to be diamonds by their form, chemical composition and physical properties.

Dr. W. von Oechelhaeuser has invented a method of converting ordinary coal gas into a very light gas which is eminently suitable for filling balloons. The process consists in decomposing and removing all of the heavy hydrocarbons and nearly all of the methane and converting the carbon dioxide into the lighter carbon monoxide. The resultant product is an almost odorless gas which contains more than 80 per cent of hydrogen and has a density of 0.2[illegible]. The density of ordinary coal gas is 0.41 and that of pure hydrogen is 0.067. The lifting power of the new gas is about one ounce avoirdupois per cubic foot, the buoyancy of coal gas is 0.7 ounce, and that of commercial hydrogen is 1.1 ounce per cubic foot. The balloon of the Aeronautical Society of Anhalt is to be filled with the new gas.

A kitten about six months old was taken to a house a few miles distant from its birthplace, confined in a room and tenderly cared for during a week, and then set at liberty. It was supposed to have become habituated to its new surroundings, but it returned to its old home on the day of its release. The sense of locality and direction was exhibited still more strikingly by an old tom cat which was stolen and carried a distance of 20 miles confined in a bag. The cat was imprisoned, but made its escape and in a few days reappeared in a pitiable state at the home of its former master, which was separated from that of the thief by a high wooded cliff.

A writer in Kosmos states that he possesses a tame magpie to which he sportively offered an extinguished cigar stump. The bird began to tear the stump apart, but apparently changing its mind proceeded to rub the stump, held in its beak, over every part of its body, including the inside of the wings, in a very careful and methodical manner. The experiment was subsequently repeated many times, always with the same result. This magpie is so fond of tobacco that it has repeatedly snatched a lighted cigar from his hand against his will. It also picks up fallen cigar ashes and strews them over its feathers. He thinks these actions have a purpose, the destruction of parasites, and are determined by atavism or inherited instinct. In the wild state some unidentified plant must have been used instead of tobacco as an insecticide. The magpie's action, furthermore, seems to be an unquestionable instance of the use of "tools" by a lower animal.

A great number of elements was studied by Madame Curie, but with the exceptions of radium, uranium and thorium she found no elementary substance possessed of a radio-activity greater than one one-hundredth of that of metallic uranium. Campbell made a similar series of examinations by a more sensitive method and came to the conclusion that potassium, rubidium and lead are radio-active, but Elster and Geitel have traced the radio-activity observed in lead to a small admixture of radium F, i. e., polonium. Levin and Ruer have recently tested the radio-activity of a great many substances. Their experiments confirm Campbell's results in regard to the radio-activity of potassium and rubidium. This radio-activity, however, is very small, being in the case of potassium only 1/1,000 of the activity of the $\beta$ radiation of uranium oxide. In this case the radio-activity cannot be attributed to impurity, as the potassium compounds examined were derived from many different sources. They included commercial compounds, potash salts obtained from molasses distillery wastes and wool washings, Stassfurt potash rock, etc. One specimen was obtained from the ashes of Russian sunflowers, a second came from the Tyrol and the third from Chile.

# A UNIVERSAL VISE.

BY JACQUES BOYER.

Vises usually occupy fixed positions and serve merely as clamps by which the wood or other material is prevented from moving while the workman is compelled to adapt the position of his tools and his body to circumstances as best he may. The ordinary vise no matter what the purpose for which it is designed consists of two jaws one fixed the other movable. The latter is moved toward and away from the former by a strong square threaded screw which turns in a nut in the fixed jaw and in a collar in the movable jaw and the movement is opposed by a flat spring which takes up the lost motion.

The universal vise invented by P Gloag en is mounted on a ball and socket joint which allows it and the object held by it to be turned in any direction so that the work can be done more conveniently and in a favorable light. When the vise has been set in the desired position the ball and socket joint is locked and held motionless by a double jointed jaw operated by a strap terminating in a loop in which the workman's foot is placed.

As the accompanying photograph indicates the universal vise is designed primarily for the use of shoemakers. It can be employed with advantage in shaping sewing nailing and almost every other operation involved in the making and repairing of shoes. The shoe and the standard which carries it can be turned into any position and instantly immobilized without touching the screw of the vise so that shaping can be done much better than is possible with a rotating vertical standard as the sole and the heel can be placed in the positions most favorable for working.

The apparatus is very simple and comprises only five large parts and two pins.

THE UNIVERSAL VISE

---

The Pacific coast lumber manufacturers have taken the initiative in an important step for the promotion of proper and conservative use of their timber supply. Practically all of the large manufacturers of lumber in the States of Oregon and Washington have entered into an agreement to manufacture odd as well as even lengths in flooring finish and similar planing-mill products. Heretofore it has been customary to manufacture these products in even lengths only. Now it is proposed to trim the manufactured lumber to lengths of odd numbers as well as even numbers of feet. Under the old system a considerable portion of the lumber which came to the shaping machine was wasted and this action has been taken in order to save that waste. Considerable opposition to this innovation has arisen among retailers and consumers. The retailer contends that it is impossible for him to dispose of odd length material because of the common practice in the construction of wooden buildings claiming that the initial saving of the manufacturer is transferred to the consumer. This is denied however because of the proportionally small amount of odd length material which will occur under the new system and because of the latter day practice of laying sub-floors of rough lumber and sheathing on the sides of the house before putting the finishing material in place. Because of the conservation element which enters into this question, the United States Forest Service has been recommending the adoption of odd lengths for some time past. The Portland office of the Service has recently made an investigation of the actual amount of unnecessary waste incident to the manufacture of even lengths only and these figures show that under the old system the refuse burner consumed about two per cent of the total amount of the important forms of planing-mill products which are manufactured from Douglas fir and other important forest species in the States of Oregon and Washington. When it is considered that about 750 000 000 feet of planing mill products are manufactured annually in the two States mentioned above this two per cent assumes important proportions. The Forest Service is authority for the statement that 15 000 000 board feet of high-price lumber can be saved annually in Oregon and Washington by the manufacture of planing-mill products into lengths of odd feet as well as even. It would require the yearly growth of timber on approximately 30 000 acres of average timber land to produce the amount of lumber which this annual waste represents. The manufacturer is convinced that the waste is unnecessary. His greatest trouble now lies with a similar conviction on the part of the consumer that odd lengths can be used as economically as even lengths.

---

The new Mexican Pan American Railway has already been opened states the American Machinist and the line is in active operation from San Jeronimo on the Tehuantepec Railway to Tapachula in Chiapas. The extension of that line will be continued to Port San Benito on the Pacific coast. There is also planned a new railway passing through parts of the States of Coahuila and Chihuahua, about 375 miles long.

# MECHANICAL BOWLING MACHINE.

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

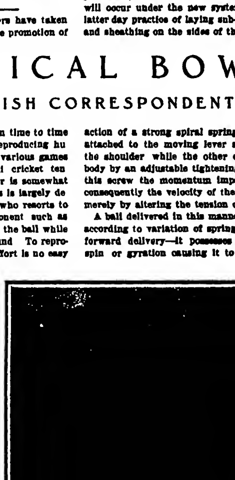
Numerous efforts have been made from time to time to devise a mechanical apparatus for reproducing human action in the delivery of a ball in various games where such is required such as baseball cricket tennis and so forth. The problem however is somewhat abstruse inasmuch as in bowling success is largely dependent upon the brains of the bowler who resorts to varying subterfuges to nonplus his opponent such as varying the pace swerve and break of the ball while in the air or after it has struck the ground. To reproduce these peculiarities by mechanical effort is no easy matter but an English engineer Mr D D Fason M I M E of Birmingham has perfected an ingenious device for fulfilling the desired purpose.

As may be seen the apparatus comprises a tripod of steel tubing firmly fixed to the ground by means of specially designed anchors which correspond to the body of the bowler. The ball rests freely in a semi spherical cup or hand carried at the outer end of a lever about the length of the human arm with which it corresponds the lower end of this lever being pivoted to the body at the shoulder.

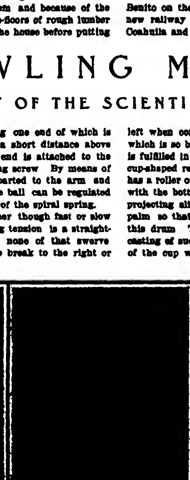
When the machine is at rest the arm remains in a vertical position and the bowling operation is produced by pressing this arm backward into a horizontal position with the ball resting in the cup-shaped hand. Directly the arm is released it flies toward its normal position describing therein a quarter of a circle the ball being propelled through the air with varying velocity as desired toward its objective. This forward movement of the moving arm is produced by the action of a strong spiral spring one end of which is attached to the moving lever a short distance above the shoulder while the other end is attached to the body by an adjustable tightening screw. By means of this screw the momentum imparted to the arm and consequently the velocity of the ball can be regulated merely by altering the tension of the spiral spring.

A ball delivered in this manner though fast or slow according to variation of spring tension is a straight-forward delivery—it possesses none of that swerve spin or gyration causing it to break to the right or left when coming into contact with the ground and which is so baffling to the batsman. This requirement is fulfilled in an ingenious manner. The center of the cup-shaped receptacle or palm of the mechanical hand has a roller or drum with its axis running transversely with the bottom of the cup and having its periphery projecting slightly above the spherical surface of the palm so that when the ball is inserted it rests upon this drum. The cup itself is fixed into a box-shaped casting of such dimensions that the external diameter of the cup will fit against the four internal sides of its containing box. Attached to the base of this outer box and at right angles therewith is a hollow spindle or tube mounted on a bearing which is rigid with the end of the arm and in which it can be revolved. It will be observed, however that the axle on which the drum revolves is at right angles with the hollow spindle on which the box and cup are mounted the spindle itself being set at right angles with the ball's trajectory. This spindle has a groove over which passes a band the ends of which lead down a recess in the arm to within a short distance of its pivot with the body and then the band is carried at a tangent over guide pulleys one on each side, and the ends looped to brackets on either side [illegible] to enable the arm to swing [illegible].

When the arm is [illegible] the "bowling" position [illegible] is pulled forward [illegible] the hand, by reason of [illegible] [illegible] [illegible]



Inserting the ball in the "hand" of the machine.



The machine in the act of throwing the ball.

A MECHANICAL BOWLING MACHINE.

# AN AUTOMATIC RAILWAY SAFETY STOP.

BY DR. ALFRED GRADENWITZ.

Since the terrible catastrophe on the Berlin Elevated and Underground Railway caused by a train running by a stopping signal, the German railway administrations have been giving increased attention to automatic braking devices for preventing the recurrence of such accidents. The apparatus illustrated in the accompanying figures has been adopted provisionally, and is now being tested out. Its object is to warn the engineer and fireman by visible and sound signals and set the brakes, all being done simultaneously.

The safety device consists of contact levers mounted on the locomotive, and pedal contacts arranged on the track. The former are always arranged on the right-hand side of the engine, and are actuated by a permanently tightened spiral spring. In the interior of the cab is arranged in a conspicuous position the repeating box, which is intended for indicating to the driver (1) whether the track is disengaged, (2) which signal has been passed over, or (3) that the apparatus is out of order, the various indications being signaled on a red background inside a white frame, immediately before the engineer's eyes.

Above this repeating box is arranged a recording box, which mainly contains a clockwork, which is actuated if the train runs by some signal. This clockwork sets a roller and paper tape rotating and thus causes a dash or dot to be inscribed. Furthermore, the engine driver is free to produce, on the same paper tape, before passing the signal, an annular mark, showing the signal to have been duly attended to. These marks may serve as useful records in the case of law-suits.

On the roof of the driver's stand is mounted an alarm siren, the howling sound of which is readily distinguished from that of ordinary locomotive whistles. The same siren is used as a braking signal in the case of brakeless goods trains. On the running board of the locomotive is arranged the brake-cock casing 5, containing, in addition to the brake-cock, a click for tightening the spring above mentioned, and, accordingly, the whole apparatus. This click, in turn, is connected through the draw-bar 10 with the contact levers 6. These two contact levers 6 on sliding over the contacts pull downward the draw-bar 10 and thus set the apparatus working. The apparatus is actuated only in the event of both levers being struck simultaneously. This arrangement thus insures thorough reliability of operation.

At each distant signal there is arranged a single pair of track contacts, and at the main signal, two pairs, situated about 30 meters apart. They are so connected with the signals as to be lifted when the signal is closed, thus protruding beyond the rail head and coming into contact with the sliding levers of the locomotive, whereas, in the event of the signal being drawn, they are located below the rail head, so as to avoid any contact.

In addition to these stationary pedals movable pedals are provided which are readily fitted behind fish plates, with a view to warn and stop trains at any point of the track.

The working of the apparatus is as follows. On the contact levers passing over the track contacts, the draw bar 10 is pulled down, thus disengaging the click. The apparatus is merely operated by the spiral spring, and as the contact levers perform no work outside of disengaging the tightening apparatus, any heavy shocks are prevented, and the wear and tear is reduced considerably.

On passing over a distant signal, the contact levers strike only a single pair of pedals situated on the track, thus closing an electric circuit, by the action of which the alarm siren is sounded, while a disk bearing the inscription "distant signal" appears in the cab signal box and a dash is marked on the paper tape in the repeating box. The brake cock is opened at the same time and the train is stopped automatically. Owing to the automatic disengagement of the brakes, the driver is in a position himself to throw the apparatus out of gear, and to continue his journey.

On a closed main signal being passed over, the contact with the first pair of pedals produces an effect, as above stated, during a very short time which effect is reinforced immediately by the second pair of track contacts. In fact, this second contact further disengages the click, thus opening completely the braking cock and producing a rapid braking. At the repeating box appears a disk with the inscription "main signal," while at the same time a dot is marked in the recording box. In addition to this, a checking lead is broken. The second contact also causes the apparatus to become locked up, so that the engine driver is no longer in a position himself to throw the apparatus out of gear, before the train guard has re-

(Continued on page 36.)

AN AUTOMATIC RAILWAY SAFETY STOP.

# FRICTION AT RAILWAY CURVES.

BY J. F. SPRINGER.

When two material surfaces are in contact with each other, there are two distinct methods of with drawing points of contact from each other Consider such points to be extremely small plane areas Thus, let Fig 1 represent a highly magnified sectional view of two contacting points *AB* represents the infinitesimal plane area (First) The surfaces may be with drawn from each other by moving *C* or *D* (or both simultaneously) in a direction perpendicular to the plane represented by *AB* This gives rise to what is termed *rolling friction* (Second) Withdrawal may be effected by moving *C* or *D* (or both simultaneously) in any one of the directions lying in the plane represented by *AB* Thus, the movement may be along *AB* The direction is immaterial, provided it is in the tiny plane of contact This method of withdrawal gives rise to *sliding friction*

Now material surfaces are not perfectly smooth When in contact under pressure, the projecting particles interlock with each other—as idealized in Fig 2 It can readily be seen that movement in the directions *G H* would tend to shear off the large projections 1, 2, 3 4, while movement in the directions *E*, *F* would tend to shear off merely the interlocking protuberances of the large projections That is to say, sliding friction involves abrasion of the principal projections, while rolling friction relates merely to projections on projections Consequently, it is not difficult to comprehend that sliding and rolling frictions belong to different orders of magnitude In fact, the one kind of friction is a most important consideration in mechanical engineering, while the other is usually negligible

It is easily seen that the movement along *AB* produces what we all understand by sliding friction, but perhaps some may hesitate at considering perpendicular withdrawal as rolling friction Consider Fig 3 Here the wheel is rolled in the direction given by the arrow *C* The removal of the points contacting at *A* is effected by the change of the instantaneous center of rotation from *AA'* to the next point *BB'* [See article "Some Principles of Ball Bearing Design" in Scientific American for November 6th, 1909] In making this change, *A* moves perpendicularly away from *A'* Likewise *B* approaches *B'* perpendicularly And so on throughout the roll—the points of contact approach and recede from each other perpendicularly to the surfaces of contact

Now it will not be very hard to see that any movement of withdrawal that is *oblique* is really a compound of the perpendicular and parallel movements. We may provisionally assume that in so far as it is perpendicular it is a rolling friction, and that in so far as it is parallel it is a sliding one That there are such compound frictions may be seen by consulting the article to which reference has already been made.

Now two very important economic questions arise in connection with friction First, friction *wears* the contacting parts This is a matter of very considerable significance Second, friction consumes *power* in performing this abrasion In some cases, this becomes a matter of still greater importance However, they go hand in hand—useless destruction of material and waste of the power used in accomplishing this destruction

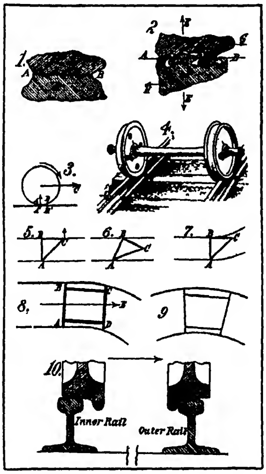
These two factors have, perhaps, been more or less recognized almost from the beginning of the age of machinery But it is only in comparatively recent years that their vital importance has begun to come to the fore. In every direction in the machine world this is testified to at the present time by the introduction of ball and roller bearings These serve—with more or less perfection—to accomplish the exchange of sliding for rolling friction In the railway world, the antifriction movement is attested by the fact that large outlays are being made to eliminate the friction at curves. Reduction of time is no doubt also in view But the railroads certainly have in view the economic gain to be derived from the avoidance of that excessive wear on rail and wheel which occurs when rounding a curve, and the money advantage in saving the steam power wasted in effecting the wear and tear

That railway curves give rise to a very excessive amount of friction may be understood from the amount of wear occurring at a certain curve in the "subway" of the Boston Elevated Railway Carbon-steel rails were replaced at a certain point, on the average, every forty four days. The amount of wearing down on the heads of these rails was about three-quarters of an inch As to what happened to the wheels in accomplishing this wear, no one has any exact information. But it must have been very considerable. Three-quarters of an inch was not worn off the rail head without a corresponding effect on the wheels and trucks.

What happened at this curve is happening, in greater or less degree, upon all curves, wherever located. It is a matter of interest and importance, then, to consider more particularly the causes of friction at railway curves.

Three prominent factors enter The first causal factor arises out of two facts The outer rail of a curved track is longer than the inner one, And yet the one must be covered in the same time as the other Then car wheels and axles are so combined that two wheels and the corresponding axle operate as a single piece. Consequently, the one wheel is compelled to rotate at precisely the same speed as the other In rounding a curve, however, a greater distance is covered by the one This conflict of rotational velocities between the two wheels results in slippage, and this of course means wear of metal and loss of power It is to be observed that this friction occurs irrespective of the speed of the train For the difference in length of rail between the two sides of the track remains precisely the same, and this controls the amount of slippage The seriousness of the friction is accentuated, however, by the speed

It has been proposed so to arrange the wheels and axle that this slippage could not occur. This might be done in two ways. Both wheels might be rotatably mounted, the axle being kept "dead"; or, the one



FRICTION AT RAILWAY CURVES.

wheel might be made integral with the axle, and the other rotatably mounted That either method would be effective can scarcely be doubted, but practical railroad people do not seem to take kindly to wheels mounted rotatably on an axle.

Whether they are justified or not, there is another friction factor which enters and which is of far greater weight. In order to get this clearly before the mind it will be well, perhaps, to consider the action of a group of flanged wheels on a railway track. Suppose we take a single pair of wheels and the corresponding axle. These wheels are flanged on the inside, as in Fig. 4 Now it will readily be granted that the axle must be kept perpendicular to the direction of the rails. In the case of the single pair of wheels, how will this be maintained? The two planes of the flanges at the places of contact with the inside of the head of the rail no doubt give some assistance. But this is practically negligible for the reason that a tight fit is not permissible. In fact, a very slight disturbance would be competent to destroy the perpendicularity of the axle, even on a straight track.

Consequently, some additional means must be utilized If we attempt to solve this problem by constructing a truck of *three* wheels, all being maintained unalterable in their relative position to each other, we should not succeed. In Fig. 5, the triangle *ABC* represents such an arrangement, the wheel contacts being supposed to be at the vertices *A*, *B*, and *C*. This truck would no doubt withstand any tendency operating to throw it in the direction of the arrow at *C*. But a tendency in the opposite direction would give rise to the situation in Fig. 6. If at no other time, such a tendency would arise at a curve in the track when the rail corresponding to *BC* tended away from the truck as a whole This condition of affairs is represented in Fig. 7

The lowest number of wheels which when combined in a truck are competent to maintain themselves upon a track is *four*. The four-wheeled truck is consequently the unit that must be dealt with in considering the friction arising at curves.

Now when such a truck rounds a curve, the outer wheel of the forward axle is the one which first meets the change of direction This is shown in Fig. 8, where the wheel at *C* has begun to respond to the curvature. The wheel at *D*, because the rail curves away from it, will tend to be relieved. The impetus of the truck is in the direction *E* Consequently, there is a severe grind at *C* And this condition obtains throughout the curve.

No doubt if, during the time of rounding the curve, the axles of the truck could always lie in radii of the curve, as shown in Fig 9, the friction arising from the rigidity of the truck formation would be largely reduced, if not entirely eliminated. Inventors seeking to attack this problem must remember that the arrangement of the truck cannot be flexible The change from the rectangular form to that of the isosceles trapezoid must be sufficiently instantaneous. It must not go further than requirements demand. Further, conditions must be reversible for curves bending in the opposite direction Altogether, this is a very pretty problem

Another factor which enters is one pointed out by Mr Edward Godfrey. The tread of the wheel is not horizontal, but inclined, as in Fig. 10. On the outside wheel of the forward axle the climbing tendency resulting from the effort of the truck to move in a straight line forces the wheel flange to some such position as that shown in the figure This is aided, no doubt, by the fact that thus greater speed is attained Reverse conditions on the inner side of the curve cooperate to the slewing of the whole axle outward, because thus a less speed is obtained on the inner side of the truck. Now the result of this slewing is to bring a very steep portion of the outer wheel in contact with the head of the rail. There arises, thus, a severe wedge action This is, perhaps, the most important of all the factors giving rise to friction at curves. It is due to a combination of the causes producing the other two.

### Death of William A. Eddy.

William A Eddy, well known throughout the country for his many kite-flying experiments, died recently after an illness of several months. Mr Eddy's life was spent in the study of kite flying, to which art he contributed much that is valuable. Although a self-taught man, he did much useful work, particularly in kite photography Latterly he was very much interested in aeronautics, to which his kite investigations naturally drew him.

Dr. Czerkis of Vienna, who has undertaken a study of the chemical structure of cannabinol, the active principle of hashish or Indian hemp, gives the following graphic description of the peculiar intoxication which hashish produces. "It is as if the sun illuminated every thought that passes through the brain, and every bodily movement is a source of joy The hashish eater does not experience the kind of pleasure which is produced by the gratification of bodily appetites. He feels the joy of one who hears good news, of the miser counting his gold, of the lucky gambler, or the successful seeker after fame. He is the sport of every impulse and the current of his thought is diverted by the slightest impression. A word or a gesture suffices to suggest new images and ideas, with marvelous quickness and precision. For this reason the Oriental hashish eater, before he gives himself up to the enjoyment of the drug, takes care to remove from his presence everything that could induce melancholy or any feeling except that of keen delight. For the accomplishment of this object he makes use of every means which the customs of the Orient place at his disposal. In his harem, surrounded by his wives, under the spell of soft music and voluptuous dances, he enjoys a delirium in which he feels himself transported to the paradise which the prophet has prepared for him."

### THE SPEED OF AN AEROPLANE PROPELLER.

The idea of propelling a huge machine weighing half a ton at the speed of an express train by means of a fan seems absurd on the face of it. One is apt to discount the power of a fan Air is such an intangible, imponderable, substanceless fluid, that it seems impossible to obtain sufficient thrust against it to drive a machine of any appreciable weight. Yet this is what a flying machine propeller must do. The result is obtained by making the propeller of such size and driving it at such speed that when the machine is held stationary, the propeller will generate a current of air flowing at the rate of a hurricane. We know something about the power of heavy gales, and when we consider that an aeroplane propeller is capable of producing a moderate-sized cyclone, it is easier to conceive of its exerting sufficient force to drive a 1,000-pound aeroplane at a fast clip Flying machines have attained a speed of over fifty miles per hour In order to do this, the propellers must have been driven fast enough to have produced a current of air considerably more than this velocity, because the fluidity and elasticity of the air is sufficient to cause a considerable "slip" of the propellers, which reduces their efficiency to a large extent, depending upon the design of the propeller Our front-page illustration this week shows Mr. Hubert Latham's "Antoinette" monoplane under going a test of its propeller The propeller is revolving at the rate of about 1,100 revolutions per minute, which is about the rate of the average electric fan, but when we consider that the propeller describes a circle 6½ feet in diameter, some idea of the volume of air set in motion by the machine can be conceived At a test made in England last fall, a thrust of 265 pounds was obtained Supposing the motor to develop only 30 horse-power instead of the 50 at which it is rated, this is equivalent to but 8.8 pounds per horse-power, which is about all the average propeller will give. A prominent American experimenter has lately obtained 325 pounds thrust with a 30-horse-power motor, but in this instance a large 9-foot propeller making but 400 R. P. M was used Such a propeller is more efficient and produces a greater thrust per horse-power In the instance cited it was also of a special form. The illustration shows Mr Farman at one side of the machine, and Mr Curtiss at the other It is curious to note that the hazy circle produced by the rapidly rotating propeller is cut at two points by wide dark bands. These are shadows cast on the blades The shadows are, of course, intermittent, as they fall upon the blades only as they come within the range of the shadows This suggests an experiment which was submitted to us some time ago by one of the readers of the SCIENTIFIC AMERICAN He proposed to show the shadow of a man on a string The proposition appeared rather startling, but he soon demonstrated that the complete shadow, showing a perfect profile of the man's face, could be shown on the string, provided the string were weighted at one end and whirled around so that it formed a hazy patch of reflected light similar to that produced by the propeller blades in our front page illustration The persistence of vision of course accounts for the haze in the first place and for the shadow as well, because both are intermittent, as an instantaneous photograph would show

### The Public Bath System of New York City.

In a paper presented before Section 1 of the American Association for the Advancement of Science, at the Boston meeting, December 28th, 1909, entitled "The Public Bath System of New York City," by William H. Hale, Ph D, Superintendent of Public Baths of Brooklyn borough of New York city, some interesting facts were stated showing the increase and utility of this recent public institution for the promotion of the public health

Prior to the consolidation of the surrounding cities into Greater New York there was no interior public bath. All were located along the river front as floating baths. The first interior public bath in Manhattan borough was established on Rivington Street on the east side of the city March 23rd, 1901, and has been the most crowded of any bath, on the average, for the year.

Newer baths opened on Pitkin and Montrose Avenues, Brooklyn borough, have had more bathers in hot weather than any others. It is stated that on one hot summer day 9,000 bathers used them. A third public bath was opened in Manhattan on November 23rd, 1904, in West 41st Street. At the present time there are seven in Brooklyn, twelve in Manhattan, and one each in the boroughs of Queens and Bronx. In the Brooklyn borough during 1908, 2,036,325 persons patronized their five interior public baths. In 1909, up to December 1st, 2,372,755 persons used all the baths in this borough, showing an increase over the previous year.

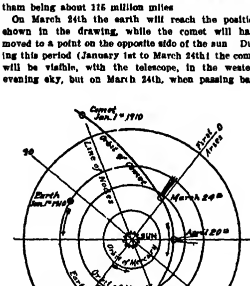
In Brooklyn a small charge is made, 1 cent for a cake of soap and 1 cent for a towel, and an additional charge of 2 cents for the use of a tub bath. The free baths are mostly of the shower kind, although in some later bath houses swimming pools have been built sixty feet long by thirty-nine feet wide, said to be the largest in the city Newer bath houses have a gymnasium built in the second story above the bath house proper. This has been found to be a most useful adjunct. Mr Hale suggested still farther that roof gardens be built above the gymnasium He also recommended that there should be a greater extension of facilities for public bathing, particularly the establishment of a great public bath by the sea modeled after the baths at Revere Beach and Manhasset Beach in Massachusetts. At Coney Island on city property such public bath structures could be constructed as would be remunerative to the city and yet would supply a pressing public want. Mr Hale further recommends the establishment of a separate bureau of public baths and gymnasiums, with uniform pay to attendants and officers, to cover the whole city The city should have full control of the proposed seaside baths, as they are intended for the entire city and not wholly for the borough in which they are located

### RELATIVE POSITIONS OF HALLEY'S COMET, THE EARTH, AND THE SUN

BY JOHN C DEAN

At the top of the accompanying drawing the comet is shown in its position for January 1st, 1910, outside of the orbit of Mars At the left the earth is moving in its orbit away from the comet, the distance between them being about 115 million miles

On March 24th the earth will reach the position shown in the drawing, while the comet will have moved to a point on the opposite side of the sun During this period (January 1st to March 24th) the comet will be visible, with the telescope, in the western evening sky, but on March 24th, when passing back



RELATIVE POSITIONS OF HALLEY'S COMET, THE EARTH, AND THE SUN.

of the sun, will be invisible for several days The distance between the earth and comet at this time will be 165,000,000 miles

When the comet next emerges from the rays of the sun it will have shifted to the morning sky, rising before dawn, and for the first time becoming an interesting object to the naked-eye observer The earth and comet will now rapidly approach each other and the latter will greatly increase in brilliancy

About April 20th it will pass its nearest point to the sun, as shown in the drawing, and on May 18th will again disappear in the sun's rays—this time, however, passing in the front of the great luminary It is predicted that the nucleus will cross the sun's disk about five minutes of a degree from its center, thus furnishing an opportunity to observe whether the nucleus is opaque to the sun's rays.

The transit will not be visible in the United States as it will occur after sunset here

On the night of May 18th the earth and comet will rush past each other and the earth will probably sweep through the tail of the comet. They will be only 12,000,000 miles apart. After May 18th the comet will attain its maximum of splendor in the evening sky, and in a few days thereafter its glory will rapidly fade.

### The Current Supplement.

Dr Alfred Gradenwitz opens the current SUPPLEMENT, No 1775, with an article on a snow plow employed on a Swiss railway Some interesting information on submarine sound signals is presented Mr Warren O. Rogers writes exhaustively on friction drums and brakes. The employment of electrolysis in chemical manufactures is made the subject of an instructive article by Prof. B. Lepsius. Mr Charles R. King describes a new gas fusion process. One of the most important questions in connection with aerial navigation is the provision of suitable places of refuge for the enormous dirigible balloons of which Germany is the proud possessor The problem is discussed in a copiously illustrated article by our German aeronautic correspondent. Dr Robert Amory writes on coffee as a beverage and describes a new method of preparing it for the table The great guano deposits of Peru are described and illustrated Dr L H Baekeland summarizes the electrical and electrochemical applications of bakelite

## Correspondence.

### THE END OF THE "DANIEL TENNEY"

To the Editor of the SCIENTIFIC AMERICAN

In looking over some old files of the SCIENTIFIC AMERICAN to-day, I found in the issue of March 13th, 1897, reference of the building of the old merchant ship "Daniel I Tenney," built at Newburyport, Mass, by John J Courier, Jr

This item, in connection with the storm now raging, carries me back to eleven years ago to-day, when the "Daniel I Tenney" was lost off the coast of Scituate, in the disastrous November gale The wreckage was strewn for miles along the shores of Scituate and Marshfield A portion of the stern containing the name was thrown ashore opposite the writer's house I picked up some of the interior finish of the cabin, and have made several pieces of furniture of it, which are prized quite highly by the owners This is the sad ending of the career of that noble ship which so proudly braved the storms of old ocean so many years.

Perhaps some of your readers may be interested to know where the "Daniel I Tenney" laid her bones to rest. W W RANDALL.

Sea View, Mass.

### THE INVENTOR OF THE STEAMBOAT

To the Editor of the SCIENTIFIC AMERICAN

I beg to thank you for publishing my letter, as also for your courtesy in sending me the copies of your current issue

I wish to point out that although I insist that it would be a most difficult matter to prove that any other of the so-called inventors have any just claim to priority, yet if any reliable proof of any "inventor" having produced a practically successful steamboat prior to 1736 is available, then I would once for all sink any claim on behalf of Jonathan Hulls, but in my humble opinion, from research I have made upon the subject, such is not possible Therefore I boldly assert that he and he alone should have the great honors ascribed to him Will anyone refute this?

I claim practical success of his invention, but not commercial success, and to do justice to an inventor's memory, it should not be for the purpose of requiring commercial success He laid the foundation for commercial success- this fact is undeniable, therefore why should he not have the honors and distinction for his genius? Always remembering that he was many years ahead of his competitors

I do not admit, what is so generally claimed, that it is not the man who invents, as the man who puts into actual practice, that is deserving of the honors. Without the man who invents, there could not be any need Neither would he have any place for putting into practice that which he would otherwise have had no knowledge of, had it not been for the earlier inventors

It appears clear that Jonathan Hulls, although the side-paddle boat had existed for many years propelled by both manual and animal labor, yet he was absolutely the first to suggest steam power to supersede both methods by steam propulsion And with his original innovation of the stern wheeler combined with the side paddles, his claim to originality is made doubly sure, always remembering the very early date of his invention and the very crude form of steam engine which then existed Therefore the greater the honor that should be accorded to him

With regard to Fulton, no serious claim can stand in face of the foregoing To put it mildly he was only a copyist in the matter of steam propulsion I cannot too forcibly assert that Robert Fulton has no claim whatever, and this fact N S Arthur Daniel corroborates This gentleman asserts that "England should certainly set up a monument for Jonathan Hulls, as he was undoubtedly the original inventor in England", and he further states "whether he actually built the boat or not is of no special consequence"

I have been able to provide proof that he did build his boat, and that it was a practical success Consequently, any additional proofs I have supporting him —and they are numerous —would be quite superfluous.

There could not possibly be more than one inventor of steam navigation, whatever adjectives be used

J HOOPER HULLS

Manor Park, Essex, England

# GLASS ESPALIER WALLS.

BY JACQUES BOYER

In the cultivation of fruits on the espalier system the trees and vines are planted along a wall of stone or brick to whi h all their branches are arefully attached so as to spread them out into a plane sur fa e an l allow free ac ess of light and air to every part Ordinarily the dire tion of the wall is deter ined by local circumstances and he varieties of pears berries  aches apricots apples and other f uits whi h are  lanted along the wall are selected with refer nce to his di rection Until very recently if the wall was built in an east and west direction so as to expose one face to the south the other face was almost  tirely wasted In order to remedy this state of af fairs several fr it grow ers have conceived the idea of employing transparent espalier walls through which the light of the sun can penetrate to the trees planted on the north side of the wall Comte Horace de Choiseni in particular has conduct ed a series of very inter esting experiments of this sort on his estate at Viry Chatillon in the Depart ment of Seine-et Oise and has obtained some very promising results He built a glass wall 6½ feet high and about 60 feet long extending in an east and west dire tion and planted fifteen pear trees of the variety Winter Doyen on ea h side north and south Tl bearing surface of the wall amounted to abo it 26 squar yards on each side The south side yielded 124 pears of a total weight of 91 pounds and the north side bore 119 pears weighing 77 pounds making in all 243 pears with an aggregate weight of 168 pounds All of the pears were of parti ularly fine a pearance without blem ishes of any kind and it is a remarkable fact that the fruit which was gathered from the north face of the wall was even smoother of skin than that which was produced on the southern side Each square yard of the glass wall produced nine or ten pears of an aver age weight of abont 11 ounces

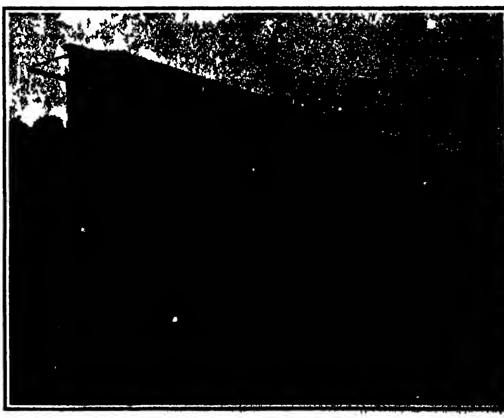
Another experiment with glass espalier walls has been made by MM Croux & Sons in their nursery at Val d Aulnay in the Department of the Seine The wall which they constr cted also lies east and west and consequently presents northern and southern ex posures As the ac om pa yi g photographs show the wall is surmounted by a glazed roof projecting on each side Along ea h fa e of the wall were  lanted Calville apples Winter Doyen Passe-Crassane and Directrer Alphand pears together with pea h trees and grape vines care being taken to place the same varieties on ea h side in order to n ake the con parison easy a d a u rate

In 1907 these trees and vines produ ed their first crop in which no differ en e betw en the fruit produ ed from the north and so th sides of the wall o ld be de e ted The same result as shown by th ro s of 1908 and 1909

There is indeed little diff rence in temperature between the north and south fa es as he former is heated by the solar rays whi h traverse the g ass and tl e latter is cooler than the so th side of a masonry wall for the very reason that some of the incident solar radi ation is transmitted through the glass and consequently less is reflected and absorbed This difference in absorbing power how ever makes the glass wall inferior to the masonry wall in the matter of warming the plants and protecting them from frost at night A masonry wall absorbs a great deal of heat during the day and gives it out at night but this effect is comparatively small in the case of a wall of glass

In the matter of cost there is little difference between the glass and the masonry walls The cathedral glass e nployed by MM Croux costs about $6 or $7 per linear yard of wall 8 feet high including the cost of the glazed roof projecting over both sides A masonry wall of the same height would cost $4 or $5 a yard and the addition of the glazed roof which of course is equally necessary in this case would raise the total cost to $6 or $7 per linear yard More extensive and long continued experiments must be made however before it will be possible to pronounce a positive opin ion concerning the relative merits of glass and ma sonry espalier walls

A GLASS ESPALIER WALL (SOUTH SIDE)



A GLASS ESPALIER WALL (NORTH SIDE)

---

There is now a prospect of a thorough, explicit cen sus of the population of China To grasp what this signifies one must first remember that China is vastly the most populous state of the whole world and second ly that hitherto such estimates of the number of its inhabitants as have been published have fluctuated between 100 000 000 and 900 000 000 only Commonly at the present day the number of natives in China is mentioned as 400 to 450 millions, but expert geographers brand this number as greatly inflated. In many late books in consequence the reader finds only 300 to 350 or indeed only 260 millions stated as the probable extent of the population Naturally it occurs to the thinker that the importance of all suppositions in regard to a yellow peril and its directions must depend very largely on a sure calculation of the size of the population of China

Of course in the course of former centuries the Chinese government projected and made at least the semblance of various censuses so that when they were published they were found to be mostly mere statements of the approximate number of families and were therefore quite unreliable And the shadowy value of such censuses was not improved by the way by the chicanery of the governments of the individual provinces who when a census was ordered for the purpose of military conscription or of collection or application of a tax promptly falsified the figures

Now finally the gigantic project of a real census of the whole Chinese Empire is to be executed and in the double form of a census of families and a census of individuals The former is to be ready by the early part of 1910 the latter by 1913 In view of the immense extent of the Chinese Empire the vastness of this task can hardly be overestimated The stupendous endeavor required by such a work can be s ustained however by the present excellent organization of the Empire though the fact cannot be ignored that certain parts of the Empire deem themselves wholly independent and will therefore resist the necessary official visitation required by the census in such districts or will try through the stiffest mendacity possible to make the results of the census as far as they concern themselves utterly ridiculous

Despite the recognition of the inevitable effect of such uncertainties and defects however the definite attempt to make a careful census of the population of China would be of great value and even if the final published result of the double form of the census were not correct by 20 to 30 million individuals

# GRAPHITE MINING IN CEYLON

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN.

Among the various minerals found in the island of Ceylon, that which is the most abundant is graphite or plumbago, practically the only one found in sufficient quantity to render exploitation profitable. It has attained a worldwide reputation for its excellent quality, its composition being practically pure carbon, and is in extensive demand for crucibles. The average output is approximately 50 000 tons per annum, the greater part of which is exported to Great Britain and the United States. Within the past two decades the trade has undergone considerable expansion with the result that mining is being extensively developed.

The mineral is found in veins and nests in the crystalline rocks occurring frequently in a fibrous or flaky form, the flakes being disposed at right angles to the wall of the vein. These veins vary in width, sometimes being less than an eighth of an inch, while in others they will extend to several feet. Some are found to follow the foliation planes of the various rocks while others run crosswise or branch in all directions. As a rule in a series of shafts sunk close to one another it will be found that a single main vein or several parallel veins will extend through the whole of these pits with minor vanes stretching from either side along the planes of division. Even if the mineral is not found in continuous veins but rather in isolated pockets or nests these are generally parallel to one of the main directions. Investigations show that the mineral exists in a series of belts but their extension can

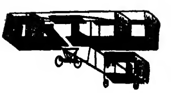
GRAPHITE MINING IN CEYLON.



# RUFUS PORTER AND HIS "FLYING SHIP."

BY C. E. McCLUER.

Soon after the Montgolfiers invented their first "hot-air" balloon, which was almost immediately followed by the first "gas" balloon, the attention of scientists and inventors seems to have been centered on the spherical and elongated gas bag as a means of flotation, and the provision of propellers and rudders to enable the navigator to control the movements of the unwieldy end wind-tossed sphere, and produce what is now known and briefly described as a "dirigible" balloon. Omitting all reference to the work of the many accomplished and venturesome balloonists who originated or copied the various devices which they adopted for the guidance and management of their spherical or pear-shaped, or elongated and cigar-shaped gas envelopes, we will revert at once to the subject of our sketch.

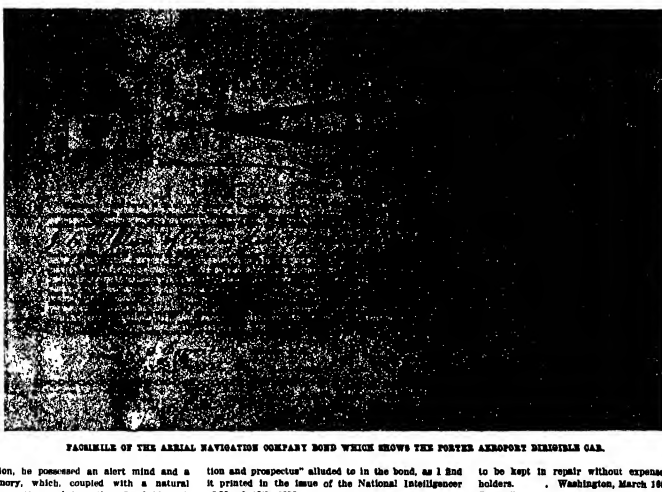
Rufus Porter, belonging to that numerous class of ingenious New Englanders usually styled "Yankee inventors," was born at West Boxford, Mass., May 1st, 1792 and died in New Haven, Conn., August 13th, 1884. Although he received only a common district school education, he possessed an alert mind and a retentive memory, which, coupled with a natural genius for observation and invention, fitted him admirably for an active and useful life. He early displayed inventive abilities of no mean order, as is attested by the list of his patented inventions disclosed by the records of the Patent Office. Some of his patents displayed an acumen and foresight which led him into the van of progress, and proved that he was fully abreast if not actually ahead of his time. Among his numerous patented inventions we find enumerated a cord making machine, a steam carriage or ordinary road vehicle, prophetic of the latter day automobile, a pioneer treadmill horse power machine, a corn sheller, the inevitable Yankee churn, a washing machine, a signal telegraph, and a municipal fire-alarm system, the latter doubtless being the forerunner of the largely adopted and efficient Gamewell fire-alarm system, now so largely in vogue.

In 1840 we find Porter as editor of The New York Mechanic, the first purely scientific newspaper published in the United States. The next year it was removed to Boston and the title changed to The American Mechanic. In 1845, evidently not having made a pronounced success with the publication of The American Mechanic he returned to New York and began the publication of another journal which he styled "Scientific American, the Advocate of Industry and Enterprise, and Journal of Mechanical and Other Improvements," on a cash capital of $100. The first number of the new periodical was issued on the 28th day of August, 1845. After six months of struggle, with varying success, his journalistic enterprise was purchased by the present proprietors of the SCIENTIFIC AMERICAN.

Among Porter's less noticed inventions, and the one from which I presume he reaped the smallest recompense, was a flying machine, or as now styled, a "dirigible" balloon, but which he dubbed an "aeroport." As nearly as I can ascertain from the records at my command, this invention was made and patented in 1820, but not until 1852 did Porter seem to make any serious effort to exploit the device. In that year he organized what he called "The Aerial Navigation Company," and attempted to raise the funds necessary to enable him to construct his first aeroport by an appeal to popular support through the sale of $5 bonds or certificates.

Among the papers of my deceased father I have recently found one of these bonds, issued to him under date of April 28th, 1852, a facsimile of which is reprinted herewith.

Below follows an abbreviated copy of the "proposal not exceed $25 per day. It is ascertained by a minute and careful estimate that an aeroport 150 feet long and capable of carrying five persons at a speed of sixty miles per hour, may be constructed for $1,500. Now, having been disappointed of the funds requisite to put this invention in operation on a scale of practical utility, I propose that if three hundred persons will subscribe five dollars each, payable when the whole amount of 1,500 dollars shall have been subscribed, I will forthwith construct this pioneer aeroport, (which may be done in six weeks), and when this is put in operation I can readily command the requisite funds for constructing a large aeroport as above mentioned. And I will so arrange that each subscriber on the payment of the said sum of five dollars, shall be furnished with a regular title deed, which shall entitle the holder thereof to one three-hundredth part of this first aeroport, and also to one three-thousandth part of the first large aeroport that shall be constructed, and of all benefits and emoluments that may be derived therefrom for twenty years, the said aeroport



FACSIMILE OF THE AERIAL NAVIGATION COMPANY BOND WHICH SHOWS THE PORTER AEROPORT DIRIGIBLE CAR.

tion and prospectus" alluded to in the bond, as I find it printed in the issue of the National Intelligencer of March 19th, 1852.

"THE FLYING SHIP."

"A chance to secure a cash income of $10 to $20 per week for twenty years by the investment of five dollars in advance.

"It is extensively known that the undersigned has by theory and practical experiments so fully demonstrated the practicability of aerial navigation that all who have fully examined the subject are convinced, and no person, even of those whose interests are adverse to its success, can offer a word of rational argument against it. Several model machines have been constructed, and each of them has operated successfully, and one of them, sixteen feet long, carried a small steam engine, by the power of which the machine was propelled, and, being guided by its own helm, travelled rapidly through the air, even against a breeze of wind, in direct lines or circles, according to the adjustment of its helm. This machine was witnessed and applauded by hundreds in New York and Boston and notices thereof were published in several newspapers of those cities at the time. Since those experiments were made the inventor has made additional improvements whereby the invention is now perfected. And it appears certain that a safe and durable aerial ship (or aeroport), capable of carrying one hundred and fifty passengers at a speed of ninety miles an hour, with more perfect safety than either steamboat or railroad cars, may be constructed for $15,000, and that the expense of running it will to be kept in repair without expense to the shareholders. . Washington, March 16th, 1852. Rufus Porter."

While with the added knowledge and experience of a half century we can see wherein Porter was mistaken in his calculations and visionary to a considerable degree, we can also see wherein he was in advance of his day and generation, and prepared to achieve the success that later and quite recently attended the efforts of Count Zeppelin and others of the present day, had he but been in possession of the gasoline or alcohol motor as now applied to dirigible balloons and aeroplanes. Comparing the fanciful representation of his aeroport as given by the engraving printed on the bond, one cannot help being struck with its resemblance to the modern dirigible balloon. While, without repeating Porter's calculations as to the capacity of his aeroport for tonnage and speed, I judge he was guilty of exaggeration, he certainly came mighty near the ideal conditions for a successful dirigible balloon with weight of engine, boiler, and cabin greatly reduced. What method he adopted for stiffening his gas cylinder in the absence of the metal, aluminium, as used by Count Zeppelin, is not disclosed, but it is quite possible an inspection of his patent might disclose some adequate provision for that purpose.

Rufus Porter is certainly entitled to all the credit attaching to the organization of his "airship" enterprise, and the exercise of his superior inventive faculties in connection with the science of aeronautics and as a pioneer in that department of human endeavor.

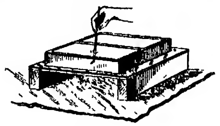
# Handy Man's Laboratory

## IMITATION MARBLE

BY A. J. JARMAN

A simple method of imitating marble with all its beautiful vein markings spots, and irregular lines and variable colors, is as follows

The skill in giving the veining, etc, to the product will be quickly attained by making a few small slabs in a plain way previous to undertaking the production of a larger number The colors for the veining must all be of a mineral character, as follows plumbago (black lead), chrome green (dark), common crocus,



IMITATION MARBLE

yellow ocher, red oxide of iron, and ultramarine blue Procure a few pieces of stout sheet glass, say 7 inches by 11 inches (an ordinary 11 x 14 photographic negative cleaned and cut in halves is just the thing) Make a wooden frame of ½ inch board, an inch deep with a division in the middle, simply held together with 1 inch iron brads not driven firmly in Leave an eighth of an inch projecting so that they can be easily withdrawn with a pair of pliers. Arrange these strips of wood, after being smoothly planed all over, so as to give two squares of five inches internal measurement.

Make up the following in a bottle Paraffin wax, ½ ounce, benzine, ¼ pint Place this, well corked in a warm room to dissolve, aid this by shaking it occasionally When the paraffin is dissolved it is ready for use. Brush some of this preparation all over the inside of the wooden panel Then take a piece of Canton flannel or soft rag, wet it with the benzine mixture, rub this well all over the smooth side of the glass plate, polish it thoroughly with two pieces of soft rag until there appears to be nothing left and place the frame upon the glass plate Now lay a mirror, or a piece of plain silvered glass upon the work bench, or table, and place a block of wood at each end so that the glass plate and frame will rest about four inches above the mirror the frame being held in place by a couple of rubber bands Place a teaspoonful of chrome green in a small saucer and a teaspoonful of black lead in another saucer and add a dessertspoonful of water to each

Mix the following in any suitable vessel (a small stoneware pitcher being well suited) To ten ounces of water add sufficient plaster of Paris to make a mixture of the consistency of thick cream Skim off the air bubbles and any dust that may float on top, when in the course of a minute or two the plaster must be poured carefully into one side of the square on top of the glass plate. Fill this nearly half way. Pour the remaining portion into the other square. Now dip a small brush into the moistened black lead, press it through the soft plaster and paint the plain or zig-zag veining or spots. The plaster blends beautifully with the color and the mirror enables one to see the effects produced. Any line made too strong or lumpy in appearance can easily be rectified by a light stroke of the brush Green streaks or veins may be painted with the same brush after washing it quickly and dipping it into the chrome green. Treat the other square in the same way.

Having now produced the veining, the block may be reinforced as follows; Have ready to hand a few pieces of galvanized iron netting. Cut a piece 4½ inches square with a quarter of an inch or three-eighths of an inch mesh. Bend up the wire ends and lay the piece down upon the plaster with rough ends sticking up. In the same pitcher that the plaster was mixed make up about the same quantity of Portland cement. Pour in the water first and then add the cement, a small quantity at a time, pour the mixture upon the plaster and wire netting until the panel is filled. Treat the second square in the same way, allow the whole to stand for an hour, until both plaster and cement have become quite set. As soon as all has become well set, draw out the brads with a pair of pliers and remove the woodwork carefully This will hasten the drying Take care not to shift the cast blocks upon the glass plate Let them become quite dry while in contact. When dry the colors will not be more than one-third as brilliant as when wet, the effect being precisely like marble The face of these blocks will possess very smooth surfaces with only a partial gloss upon them, being at the same time porous The porosity can be stopped and the gloss much improved by the use of amylacetate collodion This is practically a solution of gun cotton in amylacetate which not only fills the pores of the plaster, but forms a coating as clear and transparent as water It resists the action of weak acids and alkalies and can be washed with water and a chamois leather at any time without injury to the object it covers

When the squares are perfectly dry and slightly warm they must be placed in a plate or large saucer, containing a mixture of amylacetate collodion and one-third amylacetate This thin collodion will penetrate the pores of the plaster for a quarter of an inch or more in a short time Remove the square and stand on one corner to dry in a warm place When dry a coating of the thick amylacetate collodion may be brushed upon the surface and allowed to drain from the opposite corner The surface will improve in brightness with every coating Amylacetate collodion costs about two dollars per gallon at any wholesale chemists. A gallon will go a long way in waterproofing such slabs of imitation marble as here described

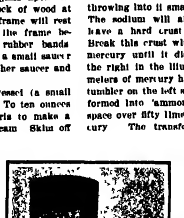
A much harder material with a slight grain can be produced by mixing a small quantity of ground pumice or ground glass with the plaster which must be intimately mixed to insure uniformity This mixture is sometimes termed Parian cement Imitation marble blocks can be made by the above process into any shape such as a keystone for a mantelpiece or circular with an inlaid border and in many other ways that will suit the taste of the individual worker In place of Portland cement, Parian cement may be used as described above, thus producing a slab of an almost uniform color Any size of slab may be made as described Of course the thickness must increase with the size of the slab to give strength

## SOME CURIOUS CHEMICAL GROWTHS

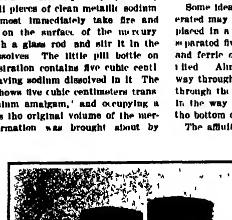
BY ALFRED P MORGAN

The following experiments are somewhat out of the ordinary but may be performed with the materials at hand in any chemical laboratory, or obtainable at a well-stocked drug store

In the first experiment mercury is prepared by throwing into it small pieces of clean metallic sodium The sodium will almost immediately take fire and leave a hard crust on the surface of the mercury Break this crust with a glass rod and stir it in the mercury until it dissolves The little pill bottle on the right in the illustration contains five cubic centimeters of mercury having sodium dissolved in it The tumbler on the left shows five cubic centimeters transformed into 'ammonium amalgam,' and occupying a space over fifty times the original volume of the mercury The transformation was brought about by throwing the mercury into a tumbler containing a strong solution of sal ammoniac in water The mercury immediately swells up into a spongy mass. The time elapsing between the moment when the sodium amalgam was thrown into ammonium chloride and the taking of the photograph illustrated here was about thirty seconds.



A SPONGE-LIKE TRANSFORMATION OF MERCURY.



PLANT-LIKE GROWTHS DUE TO OSMOTIC PRESSURE.

The reaction may be represented as follows "(Na dissolved in Hg) and $NH_4Cl$ = ($NH_4$ dissolved in Hg) + NaCl.

Upon examination of the mass, it is seen to be very spongy in nature, and its growth in all probability caused by the evolution of a gas. This is indeed the true explanation of the phenomenon The $NH_4$ of the ammonium chloride dissolves in the mercury but soon the mass decomposes, and bubbles of ammonia and hydrogen gas cause the enlargement.

In a few moments the mass will begin to sink, and a strong smell of ammonia will be noticeable If a lighted match is held over the small bubbles arising from the liquid, they will burn, lighting with the "pop" indicative of hydrogen The mercury will soon return to its normal condition, in accordance with the following equation

$$2\ NH_4 \text{ dissolved in } Hg = 2\ NH_3 + H_2 + Hg$$

There can be no doubt that the $NH_4$ is actually present in solution in the mercury, for when a salt of ammonium is decomposed by electrolysis, the $NH_4$ ion upon its discharge gives ammonia and hydrogen and no $NH_4$ is formed But if a pool of mercury is used as the negative electrode the $NH_4$ dissolves in the mercury and forms an amalgam with it However, during the formation it swells up and gives off the products mentioned above

GROWTH OF ALUMINIUM OXIDE ON A TELEPHONE RECEIVER.

The most interesting point about this experiment is that it is in accordance with the theory that ammonium would have the properties of a metal if it could be isolated for excepting this substance the metals themselves can only be dissolved in mercury

The second photograph is an illustration of an experiment depending upon the peculiar property of aluminium amalgam

The action of sulphuric and nitric acids upon ordinary aluminium is very slow because the metal receives a coating of aluminium hydroxide and is shielded from the acid, but if the aluminium is amalgamated with mercury, the action is very rapid

Aluminium has a very great affinity for oxygen, and will displace all the metals save magnesium from their oxides If a mixture of aluminium powder and ferric oxide is placed in a crucible, and fired by means of a piece of burning magnesium, a violent reaction takes place enough heat being produced to leave the iron, which is one of the products in a highly molten state This is the principle of the "thermite" used for welding, etc

$$Fe_2O_3 + 2\ Al = Al_2O_3 + 2\ Fe$$

Some idea of the speed of reaction and the heat generated may be gained if three small iron crucibles are placed in a vertical column, one above the other and separated five or six inches A mixture of aluminium and ferric oxide is placed in the top crucible and ignited Almost immediately molten iron will melt its way through the bottom of the first crucible and pass through the second and third as if there was nothing in the way A box of sand should be placed beneath the bottom crucible to catch the molten metal

The affinity of aluminium for oxygen can be shown by amalgamating a piece of the metal with mercury The surface is almost immediately oxidized and the result is a growth of white tufts of aluminium oxide over the surface of the metal where it has been amalgamated The growth will rise about one-eighth of an inch or more in five minutes.

The easiest method of amalgamating the aluminium is to clean a small portion, and then drop upon it some mercuric nitrate solution and allow it to dry The growth will immediately commence

In the illustration, the case of an aluminium backed telephone receiver has been used for the experiment, and the resulting growth is shown by the white spots, principally on top at the left

The third photograph is a striking illustration of osmotic pressure The tall plant like growths may be formed by throwing small pieces of any of the following crystalline chemicals ferric nitrate copper chloride cobalt nitrate, nickel sulphate and manganese sulphate into a beaker glass containing a diluted solution of sodium silicate of 1.1 specific gravity The crystals will almost immediately sprout up into various fantastic shapes, and grow several inches in the course of a few minutes.

The salts dissolve in the water of the sodium sili

cate solution and react with the sodium silicate to form a silicate of the metal of the salt added For instance in the case of copper chloride copper silicate is formed

$$CuCl_2 + Na_2SiO_3 = CuSiO_3 + 2\,NaCl$$

Silicate of copper is insoluble and so the result of the reaction is a small portion of liquid around the crystal of $CuCl_2$ surrounded by a sack of insoluble $CuSiO_3$ where the copper chloride has come into contact with the sodium silicate

Particles of a *dissolved substance* exercise a pressure similar to that of a gas explained in physics texts under the title of the kinetic molecular hypothesis

When the sack is first formed the pressure is equal on both sides but as more of the copper chloride dissolves the pressure on the inside of the sack becomes so great that it bursts at the top where the *hydrostatic* pressure of the liquid is least and the sack weakest

The liquid spurting out of the top is immediately surrounded by a new sack and the process continues until the salt is exhausted or the growth reaches the surface of the liquid

The silicates of the metals of the salts mentioned in the list above are also insoluble and the same explanation holds true for their action

## WIRELESS EXPERIMENTS WITH A STATIC MACHINE

BY E. H. WILLIAMS, JR.

In the large quantity of literature on wireless telegraphy practically the only method described of producing the high tension currents required is that of using a powerful induction coil or a high tension transformer on an alternating current The possibility of utilizing the discharge from a direct generator of static electricity is barely touched upon In order to test the practicability of the use of such a source of current the writer constructed a static machine of the Wimshurst pattern and made some experiments with it The machine a photograph of which is shown herewith was fitted with two glass plates twenty inches in diameter supported on a half inch steel shaft Each plate had thirty sectors of heavy tinfoil 3½ inches long The brass work was made from 3 16th round rod and the brass balls on the collectors and Leyden jars were purchased from a manufacturer of brass bed steads as were the large balls terminating the discharge rods and the sending device below These balls were filled with crushed tinfoil and contact made by inserting the supporting rods in wooden bushings fitted in the necks of the balls

The two Leyden jars showing at the front of the machine were made from hydrometer glasses provided with feet and each had a combined inner and outer coating of 65 square inches of foil The interior coatings were arranged to be connected with the discharge rods by short loops of brass chain and the exteriors joined with a similar chain laid along the base of the machine The device shown attached to the front support is the key by which the spark is thrown into the aerial and ground and the messages sent By pressing the lower lever the rocking arm above it which supports the two insulated balls is pulled upward and the latter are thrown into range of the spark from the discharge balls One of the key balls is connected to the aerial and the other to a good ground such as a gas or water pipe I found it best to allow the aerial ball to take its charge from the positive discharger By pressing the key for longer or shorter intervals the dots and dashes of the code are easily obtainable

An aerial was erected on my roof at a height of 45 feet above the ground consisting of two horizontal copper wires supported on two-foot spreaders with leads off near the center running to the edge of the roof where they were joined and a single wire led thence to the machine on the third floor This aerial gave a wave length of about 72 meters Owing to the extremely high tension and evanescent nature of the discharge it was necessary to insulate the wires with great care which was done by supporting them in paraffin lined glass tubes The machine as constructed gave a solid stream of bright two-inch sparks resembling those from an induction coil when the large dischargers balls were used and the jars unconnected With the latter in circuit in the usual manner a very thick loud and powerful spark of about the same length was obtained at intervals. With a large ball on the right hand rod and a small one on the left, a much thinner and more frequent spark from five to six inches long appeared

The first experiments in sending messages were conducted with the receiver in a room about thirty feet away from the machine, using a gaspipe ground and

Fig 1—GRATING WHICH GIVES THE COLOR ILLUSION

no receiving aerial A number of detectors were constructed experimentally including a coherer and de coherer with a ¼ inch gap filled with nickel silver filings a microphone consisting of a piece of hard pencil lead bridging two steel needles a bare point electrolytic and a Marconi magnetic detector In all the tests made the coherer gave the best results at short range and the microphone the best for longer distance Indeed the sounds were much clearer in this case than when the electrolytic was used though the latter is considered the most sensitive of all

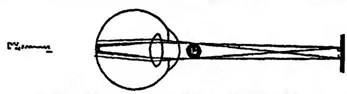


Fig 2—DIAGRAM EXPLAINING THE COLOR ILLUSION

In these experiments a home made relay of 200 ohms resistance was used with the coherer and a pair of 75-ohm ear phones with the microphone In the experiment conducted in the near by room the straight spark from the discharge balls was used and gave clear signals The coherer was then moved to the back yard and provided with a ten foot aerial stretched horizontally six feet above the ground the other connection being to a water pipe The signals were still received clearly but on increasing the distance to three hundred yards no result was obtained with either receiver although the aerial was extended to a length of thirty feet

In order to increase the power of the spark the inner coatings of the jars were connected to the dischargers the outer coatings still remaining unconnected

By this arrangement a shorter thicker and more brilliant spark was thrown into the key balls which while not as frequent as in the former case was sufficiently continuous to easily permit sending distinct dots and dashes when the machine was driven at a slightly higher speed The microphone now responded clearly when the key was worked showing the increase in efficiency of the new arrangement and a more ambitious experiment was decided upon The receiving station including microphone telephone receiver tuning coil batteries, etc was transferred to a house three-quarters of a mile away and a receiving aerial erected As the owner of the house objected to the use of the roof for this purpose I was compelled to put up a [illegible] aerial of a vertical type, projecting from a third-story rear window

Three clothes props were spliced together for a support, and a three-foot spreader fixed at the top, from which were suspended a pair of copper wires thirty feet long These wires were joined at the bottom and led to the tuning coil, which had a capacity of 125 meters and thence to the microphone At a prearranged hour my better half patiently worked the static machine at the sending end for fifteen minutes, sending dashes at slow speed and in groups of three, to avoid confusion and these signals could be faintly but unmistakably heard in the phones at my end.

I have no doubt that with a more efficient aerial, variable condenser high resistance head phones, and potentiometer for the battery the receiving distance could be enormously increased Possibly a zinc spark gap and sending helix would be an advantage at the sending end A multiple machine, having three or more pairs of plates would probably have sufficient capacity to rapidly charge and discharge a small pair of Leyden jars and so send greatly increased power into the aerial and increase the radius of efficiency The details of the spark gap showing the character of the spark as given from the interiors of the jars alone as used in the foregoing experiments are shown in one of the photographs The receiving apparatus with the exception of the tuning coil is also shown herewith

## A COLOR AND RELIEF ILLUSION

BY PROF GUSTAVE MICHAUD COSTA RICA STATE COLLEGE

Hold a pin vertically with its pointed end between the thumb and forefinger Place the pin thus held before your eye in contact with your eyelid Close the other eye and look at the drawing Fig 1 this being at a distance of about three to five inches from your eye

Two differently colored gratings apparently placed at two different distances from the eye both of them made up of vertical lines will immediately appear One seems to be relatively near Its lines have a dark brownish hue The other is made up of dark bluish bars and every one of these seems to stand at a distance behind the first grating If the figure be moved laterally the near-by brownish lines are seen to move on with the paper but the bluish bars run in the opposite direction

The near-by brownish bars are the black stripes of the figure In spite of the fact that the distance between the figure and the eye is shorter than that of distinct vision the stripes are not much blurred as the pin decreases the aperture of the pupil and thereby increases the depth of focus

The far away bluish bars are the shadows cast by the pin on the retina in the middle of every luminous beam sent by the corresponding white line The shadow is cast right side up but the retina inverts it and the result is the curious inverse motion of the bluish bars when the paper or pin is made to travel laterally

The origin of the bluish color of these bars is shown on Fig 2 $L\ L$ is the cross section of a white line The pin $P$ (relative size is exaggerated) closes the central part of the crystalline lens and as the achromatism of the periphery is imperfect there is a rather strong dispersion of the white light The blue rays $B\ B$ of the shaded spectrum invade the obscure central zone which is the shadow of the pin This assumes a bluish hue For a similar reason the less refrangible colors red and yellow lag behind and remain on the image of the black stripes right and left of the white line The admixture of colored light to the dark stripes is increased by the fact that the whole image being out of focus the limit between the black and white lines cannot be sharp

The blue rays meet to a focus before the red and yellow rays they give therefore the impression of coming from a far-away luminous object. The contrary statement is true for the red and yellow rays. This accounts in part for the fact that the brownish bars seem to be nearer than the bluish lines. The writer confesses however that this explanation does not entirely satisfy him

Indestructible black ink is made from 1 part lampblack, 12 parts water-glass of syrupy consistency, 1 part [illegible]

RECEIVING APPARATUS, SHOWING THE MICROPHONE DETECTOR.

PHOTOGRAPH SHOWING CHARACTER OF SPARK DISCHARGE.

THE WIMSHURST [illegible] AND THE TRANSMITTING KEY.

## RECENTLY PATENTED INVENTIONS.

### Electrical Devices.

SANITARY TELEPHONE-TRANSMITTER.—M. E. Calloty, Seattle, Wash. The mouthpiece in common use is a most prolific source of disease caused by the accumulation of germs therein. This is especially the case with public telephones. The invention provides a device which will take the place of the ordinary mouth-piece and it is covered when not in use, thereby preventing the accumulation of dust or germs. The transmitting members may be cleaned automatically and disinfected each time after use.

### Of Interest to Farmers.

COMBINED DISK AND SHOE SEEDING DEVICE.—N. L. Heckman, Marion, Ind. In the present patent the invention has reference to improvements in combined disk and shoe seeding devices, and has for its object to produce a device in which the lower seed conduit or shoe forms a part of the furrow opener and deposits the seed at the periphery of the disk.

WEED-ERADICATING MACHINE.—B. F Scott and J A Scott, Jasper, Minn This machine extracts weeds, roots, rubbish, etc., from the ground, and delivers the above materials into a receptacle by means of a structure which carts it from the field The structure is resilient, thereby avoiding breakage of the machine parts, and the machine is simple and inexpensive in structure

COW STALL.—C S. Torrey, Bellevue, Mich The invention affords a triangular rear wall for a manger, a trench at the rear of the stall for the reception of excrement the rear wall of the manger preventing a stalled animal from stepping too far forward, and there are adjustable means for preventing the animal from stepping backward into the trench while occupying the stall.

APPARATUS FOR MAKING AND PACKAGING BUTTER.—J De Lisle, New York, N Y The object in this case is to provide an apparatus for making and packaging butter aseptically, that is, absolutely free from microbes liable to produce fermentation or putrefaction in the butter or disease in the intestines or other organs of the consumer of the butter

### Of General Interest.

EMBALMING INSTRUMENT — T F Riley, Troy, N Y The improvement is in instruments for use in draining the blood from the body in the process of embalming, and the purpose is to provide a device adapted to conform to the curves of the circulating organs, whereby it is possible to reach points ordinarily inaccessible and draw the blood off from two or more places simultaneously

NON-REFILLABLE BOTTLE.—H C. Anderson, Unionport, and F B. Aall, New York, N Y The object of the invention is to provide a durable bottle from which the contents can be easily poured, which cannot be refilled after once being emptied by the ordinary methods, such as by force, submersion, or by the use of a vacuum, and the form of which does not differ radically from that of the ordinary bottle.

PICTURE-FRAME.—E. Oldenbusch, New York, N Y More particularly the invention relates to that type of frame commonly known in the art as a "shadow box." The frame is adapted to hold any form of picture, plaque, photograph, medallion, etching or the like, and is so constructed that the picture is spaced at a considerable distance back of the glass.

NON REFILLABLE BOTTLE.—J Bierma, Elizabeth, and E. J Heil, Carteret, N J The aim of the improvement is to produce a bottle having a simple construction which will operate normally to prevent the bottle from being refilled, but which may be manipulated in such a way as to open readily to allow the liquid within the bottle to be poured out

WATER-CURB-BOX LID.—J J Heimbuecher, Pittsburg, Pa. The lid comprises segmented sections hinged together at one edge, with fastening means at an opposite point and provided with depending hook like lugs to underlie a flange on the box the sections combining to form a circular plate adapted to cover a curb box when the lid is lost.

FRAME-JOINT AND METHOD OF SOLDERING THE SAME.—L. B. Prahar, New York, N. Y. This invention relates to improvements in frame joints, and more particularly to a new method of securing together the abutting ends of metal channels going to make up the frame. It may be utilized in joints for bag jaws, picture frames, etc.

NON-REFILLABLE BOTTLE.—A. La Rosa, New York, N. Y When the device is ready for use the operator inverts the bottle in order to discharge the contents, and may remove the cap or not, as desired. The liquid finds its way out around the balls loosely mounted within the valve casing, as it has a clear open passage for this purpose. When, however, the bottle is placed in normal erect position the balls effectively seal the bottle and prevent entrance of any liquid.

### Hardware.

HASP-LOCK.—P. McMenamin, Jersey City, N. J. This lock may be generally defined as consisting of a staple or other keeper, a hasp adapted to swing into and out of engagement with the keeper at one side of a plane passing through the keeper and the point of pivotal support of the hasp, and a lock to lock the hasp to the keeper, hinged to the hasp to move independently thereof to and from locking position at the opposite side of the plane when the hasp and keeper are engaged.

SQUARE.—T C. Howland, Long Branch, N J The arms of this square may be stamped out or cast from any suitable metal, and when assembled maintain their proper angular relation by providing one of the arms with a longitudinal channel having a branch at or near one end extending through the side edge of the arm, and with the bottom of the channel provided with a slot forming flanges, and the other arm having a portion closely fitting and conforming to the channel and the slot and seated on the flanges.

FAUCET.—H Forman, Fresno, Cal. An object of the inventor is to provide a device by means of which fluid can be drawn from a tank or other receptacle, and which simultaneously permits the introduction into the receptacle of an amount of fluid corresponding to that withdrawn.

### Heating and Lighting.

BOILER TUBE EXPANDER.—J C Tassey, Nashville, Tenn This expander is for use for pressing boiler tubes into boiler sheets. An important feature is the means whereby a cover sleeve fitting over beading rolls may be advanced over said rolls to bear against the flue sheet and permit the projection of the flue beyond the flue sheet during operation of expanding the wedges within the flue after which the cover sleeve may be released and adjusted back over the rolls away from the flue sheet so the rolls may operate on the projecting portion of the flue to bead the same into engagement with the flue sheet

VALVE.—W Shoatleff, Moline, Ill The aim of this inventor is to provide a valve, especially adapted for use with vapor heating apparatus for controlling the supply of vapor to the coils of the radiators, and wherein the size of the opening for admitting the vapor may be contracted or enlarged without the use of special tools.

### Household Utilities.

ELEVATOR-CUPBOARD.—C H Weller, Canton, Pa In this instance the invention is an improvement in elevator or disappearing cupboards such as embody an elevator shaft frame in which the cupboard is vertically movable, the shaft frame being erected directly below an opening in the floor of the kitchen or other room where access to the cupboard is to be had.

WINDOW CLOTHES-LINE SUPPORT T A. Macdonald, Clifton, N J Mr Macdonald has devised a support adapted for attachment to window frames by means of a universal joint whereby it is adapted to be swung into different positions as required to enable clothes to be easily placed on or removed from the line, and to be swung into horizontal position when not for use.

SUPPORT FOR SAD-IRONS.—G Ellstrom, Pittsburg, Pa. A hot sad-iron cannot be left standing for an appreciable time upon an ironing board without scorching the fabric upon which it rests. The invention gives a support for the iron while the user is spreading out the article to be ironed. When in non-service position the device is not cumbersome or in the way

TRUCK STRUCTURE FOR GARBAGE OR ASH CANS.—M. T Lyon, Salt Lake City, Utah The object of the invention is to provide a structure for garbage or ash cans which will enable the latter to be conveniently handled and transported from one place to another, as from a house to the alley, with little effort In this structure the wheels are securely fastened to the body by simple means.

CHERRY PITTER.—F E. Greene, Courtland, Cal The object here is to provide a pitter that will remove the pits from cherries without mutilating the cherries. Another object is to provide a pitter which will remove the pits without punching holes through the cherries, thus saving considerable fruit.

### Machines and Mechanical Devices.

ADVERTISING APPARATUS.—A Weinmann, Berlin, Germany In this device an endless sheet bearing the advertisement is employed It travels over rollers, the driving gear of which includes a clutch coupling and there are illuminating elements which are controlled by the actuating devices of the clutch coupling, for periodically lighting the advertising device

PAPER-FEED FOR TYPE WRITERS.—E. S Mansfield, Atlanta, Ga This improvement relates to a paper-feeding device for typewriters and the object is to provide a device of this class which can be readily attached to a typewriter of ordinary construction, and which will operate to hold a number of sheets of typewriter paper and advance the same in succession to the platen.

VALVE.—W. N Long, Eugene, Ore. This valve is for use in flushing tanks. The valve has a cup movable in relation to an inlet pipe, this cup being provided with a hood for preventing excessive splashing of the water when the cup is raised for the purpose of allowing water, under considerable pressure, to refill the tank.

MECHANICAL STOKER.—E. V. Elliott, New York, N. Y. This stoker is arranged to crush or reduce coal to a fine mesh, to distribute the reduced coal uniformly over the grate surface in the fire box, to insure proper burning of the fuel and complete combustion thereof, to agitate the grate constantly at slow motion with a view to keep the fire clean from dead ashes and prevent coking, and to automatically remove the ashes from the furnaces.

GEARING.—H M Baker, Jr., New York, N Y The invention refers to speed-controlled signaling mechanism, the more particular purpose being to provide a device in which a predetermined speed in a revoluble member forces into or out of action a visual signal so that a person may, by glancing at the signal, tell whether the speed is above or below a predetermined critical point

AUTOMATIC SAFETY ELEVATOR DOOR OPENER AND CLOSER.—F F Boyd, Philadelphia, Pa. The main object of this improvement is to provide a device which will be operated by the elevator itself to open the door when the elevator stops at the adjacent floor and to close it immediately when the elevator is moved up or down

WATER-MOTOR.—W J White, Oyster Bay, N Y The motor is adapted to utilize a small current of water having sufficient head so that a considerable power can be derived The invention contemplates an arrangement of tanks or reservoirs in which the water level rises and falls continuously Automatic means are provided for operating valves which control the flow through the reservoirs or tanks so that the motor operates continuously to develop energy

COMBINATION LOCKING MECHANISM.—H Van Hoevenberg, Lake Placid, N Y The invention refers to certain improvements in locks for boxes or other containers, and more particularly to that form of lock in which the two sections or parts, for instance the box and cover, are rotatable in respect to each other, to operate the lock.

ORE GRINDING MACHINE.—J C Tatman, Denver, Colo The object of the invention is to provide a machine arranged to provide a revolving velocity of the grinding wheels or mullers sufficiently high to take up and throw the wet ore particles at a tangent against the enveloping screen and to render the machine non sliming

REVERSING MEANS FOR SHAFTS.—H F Snyder, Perry Township Pa The invention pertains to certain improvements in reversing mechanism, and more particularly to means whereby the momentum of the engine while slowing down stores up energy to start the engine in the reverse direction as soon as it comes to a full stop

PAPER SLITTER.—S M Langston Camden, N J The machine is designed for cutting or slitting a strip of paper into a plurality of narrower strips and rewinding the narrower strips side by side upon a suitable reel A special feature resides in the rewinding mechanism and the means employed for maintaining uniform surface friction upon the rewound strips during the entire rewinding operation

SOUND BOX.—W A Chapman, Smithville, Ark An object here is to provide a box for reproducing or recording the sounds by means of records, employed in phonographs, talking machines, etc, by means of which the sounds can be reproduced with clearness and distinctness, and with all their original tonal qualities, and in which the relatively movable parts are not subjected to excessive wear

TYPE WRITING MACHINE.—H G McCool, Carmichaels, Pa. This inventor received former Letters Patent of the U S for a syllable keyboard for typewriters and type-setting machines, in which the keyboard has 192 keys, the same being arranged in twelve horizontal rows of sixteen keys each, and each key bearing three symbols to wit a single letter and two syllables of two and three letters respectively By its use great speed is attained The present invention is provided with such keyboard, or practically the same

WIND-MOTOR.—R F E Okrassa, Antigua, Guatemala The intention of this inventor is to provide a wind motor, arranged to utilize the power of the wind to the fullest advantage to hold the wind wheel accurately in the wind, to protect the wind wheel in case of storms and to properly transmit the power of the motor to other machinery

MECHANICAL MOVEMENT.—W S Allan Monterey Mexico. The invention has reference to a suitable motion for the operation of a pump having two plungers working in one cylinder one above the other and is especially designed to be operated by a windmill or to be used as a pumping jack in connection with other power

SAFETY DEVICE FOR ELEVATORS.—E. T Danskey, Topeka, Kan This device is particularly useful in connection with elevators operated by means of hoisting cables By means of the device an elevator can be instantly brought to a full stop in case the hoisting cables or mechanism gives way, and which is directly controlled by the hoisting cables.

### Prime Movers and Their Accessories.

DOUBLE-ACTING INTERNAL-COMBUSTION ENGINE.—H. O Hoehne and J. F Boyland, New York, N. Y In the present patent the invention is an improvement in double-acting internal combustion engines and belongs to that class of engines in which the driving-shaft is operably connected with the piston through slots in opposite sides of the cylinder

STUFFING-BOX GLAND.—F Kessler, White Plains, N Y The invention has in view a gland in which the sections interlock with each other and are held against relative movement in any direction the bolts or studs for forcing the gland into the stuffing box also serving to force the inner end portions of the sections of the gland together

### Railways and Their Accessories.

MAIL-CATCHER.—A M Bridgewater, Denver, Colo The invention pertains to apparatus adapted to deliver and receive from railway trains mail bags and the like It is a device in which the delivery means, both on the train and on the ground is in the nature of a crane, and the receiving means is in the nature of a combined guide and receptacle

TRACK SANDER.—D Tatarian, New port R I In the present patent the object of the inventor is the provision of a cheaply constructed and simple track sander for use with passenger cars so arranged as to be conveniently operated and easily filled with sand, and which may be applied to existing cars with but little cost.

SLIDING DOOR FASTENER.—F J S. Mibly, Gunnison, Colo The fastener is designed more especially for box car doors which are mounted to slide and to swing outwardly at the bottom on the door hangers The invention consists of door brackets door jamb keepers, a cross-shaft having eccentrics journaled in the brackets, and a hand lever to revolve the shaft into and out of locking engagement with the keepers

STATION INDICATOR F L. Pitts, Yuma, Ariz. This invention relates to means for indicating the stopping places along railways, street car lines and the like and the object is to provide a device which may be located in some conspicuous position which may be operated by the brakeman or other employee so as to indicate the next point at which the train will stop

SCREENING APPARATUS.—J H Lynch, Haverstraw, N Y The invention refers more particularly to an apparatus designed for use in screening sand gravel coal or the like into two different grades and delivering each to a separate car or receiver It is designed to be so mounted that cars may be run along separate tracks beneath the apparatus and as soon as filled replaced by empty cars upon the same tracks.

### Pertaining to Recreation.

BILLIARD CUE TIP AND FASTENER.—P Marx New York N Y In this instance the object of the invention is to provide a new and improved billiard cue tip and fastener for use on cues with or without ferrules and arranged to securely hold the tip in position and to allow convenient replacing of a worn out tip

GAME APPARATUS.—H O Schreiber and C A Gintz, East Liverpool Ohio. This invention is an improved toy being in the nature of a miniature or table basket ball game The board may be constructed oblong for two players or square hexagonal or octagonal for four, six or eight players. The game may be played for goals and rules may be adopted to suit the players and copied from the basket ball rule book

PISTOL.—M J Sillimer Bethlehem Pa The invention provides a cap roll support at a point on the toy pistol such that the roll will be immediately accessible to and at all times within view of the operator and further to so blanket the firing anvil when it is struck by the hammer that the possibility of flying fragments of the cap is eliminated

### Pertaining to Vehicles.

EMERGENCY WHEEL-RIM.—W F Jenkins and R L Jenkins Richmond Va The invention relates to attachments for wheels using pneumatic tires, and is particularly applicable to the wheels of automobiles and similar motor vehicles An object is to provide an auxiliary rim which can be attached to the rim of the wheel and which relieves the injured tire from the weight of the vehicle An attaching means is provided so that the working parts are kept from rattling when not in use

### Designs.

DESIGN FOR A PLATE OR SIMILAR ARTICLE.—C Zieoura Limoges France In this design for a plate or similar article the plate rim is octagonal in form the various separated angles in which it is laid out being in two alternating lengths A scroll work ornamental border runs around the edge of the article

DESIGN FOR A QUILL HOLDER FOR LADIES' HATS.—H W Schwarz New York N Y.—This design shows an ornamental quill holder The article is flanged at the top and narrows almost to a point at the bottom the whole taking a semi-circular form with two different patterns for graceful ornamental effect

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

# Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th or will be sent by mail on request.

(12163) J. V S. says Kindly help us in an argument. We agree upon the fact that the upper part of a wheel travels faster than the lower part when the wheel is pushed along a road Kindly state if the same conditions do not prevail when the wheel is driven from the center, as is the case with the rear wheel of an automobile A The motion of a wheel is exactly the same whether driven in one way or another, from the center or dragged by a horse It simply turns around the axle. The angular velocity of every part is the same as measured from the center line of the axle. Since the part of the wheel in contact with the road is at rest on the earth or rail, the top of the wheel is moving twice as fast as the hub, as referred to the point of contact with the earth We have fully discussed this in Answers to Queries, Vol 92, Nos. 16, 20 in the Correspondence Column of Vol 92, No. 25, and in Vol. 96, No. 6, price 10 cents each.

(12164) J T S says Will you kindly tell me how I can improve the acoustics of my recitation room? It is 67 feet long, 30 feet wide, and the ceiling is 18 feet high There is nothing in the room but the recitation tables, a blackboard, and fifteen electric light drops hanging from the ceiling The room echoes so, it is almost impossible to carry on a recitation, or hear anyone speak A Your case is a difficult one, the room is as badly proportioned as it can possibly be It would be much better if it were divided into two rooms by a partition across the middle of its longer dimension. It is more than twice as long as it is broad, a tunnel in fact The usual remedy for echoes is to hang soft curtains or other drapery upon the walls to interfere with the reflection of the sound waves. This would doubtless cure your room but the cure is expensive

(12165) J H B says 1 What is the highest resistance that an ordinary dry cell can overcome? How much current will an electromagnet wound to four ohms resistance use? Also, will one wound to twenty ohms use more or less current? A The current which a dry cell can send depends upon the resistance of the circuit in which it is placed. The voltage of a dry cell should be about 1 4 volts. Against a resistance of 4 ohms this cell can send about 3 amperes found by dividing 4 by 1 4 This is in accordance with Ohm's law If the resistance is higher, the current is less. If there are 20 ohms, the current will be only a fifth as much as with 4 ohms. A dry cell can send a current which can be detected by a delicate instrument even when the resistance is many hundred ohms. That depends on the sensitiveness of the instrument 2 What size wire and how much will be required to wind a magnet of four ohms resistance? A The size of wire for an electromagnet must be selected for the current which is to be used in the magnet If you use No 24 wire you can take 40 feet to the ohm 1 What is the best way to make and charge a permanent magnet? A To make a permanent magnet get a piece of good steel tool steel is ordinarily used—and harden the ends glass hard. Then draw the bar across and off from the pole of a strong magnet It will be magnetized so that the end of the bar which leaves the magnet last will be a pole opposite to that of the magnet The bar should be drawn across the magnet pole 15 to 20 times.

(12166) J H C. says Steel resists the power of magnetism more than soft iron and heat destroys the magnetism of a steel magnet Now suppose you heat a piece of magnet steel and temper it properly while in a powerful magnetic field will the point of magnetic saturation be raised or lowered, or will it be the same as if magnetized at ordinary temperatures? A If steel is heated till its magnetism is destroyed, and then tempered in a strong magnetic field, its magnetism will be restored and if the field is strong enough, the bar will be saturated The degree of magnetism which constitutes saturation will not be affected by such treatment Saturation depends upon the kind of steel and the magnetic force to which it is subjected.

(12167) H A B. says 1 Would you kindly tell me how large a spark would a Wimshurst influence machine give which has 16-inch plates, each having 16 segments on them of tinfoil? A A static machine Wimshurst or Holtz, may give a spark as long as the distance between the sectors at their nearest points across the axle Without Leyden jars the spark is a thin blue line. With the jars the spark is shorter, but far more intense. It is the spark due to the heavy discharge of the jars 2 Could I increase the length of the spark by Leyden jars or by adding more segments to the plates? A. You have the proper number of segments upon your plates at present. You will find in our Supplement Nos. 778, 279, 283, valuable articles upon the Holtz machine, with many experiments; and in Supplement Nos. 548, 584, 647, 814, 842, 1181, valuable articles upon the Wimshurst machine. We will send the papers for ten cents each.

# INDEX OF INVENTIONS

**For which Letters Patent of the United States were Issued for the Week Ending December 28, 1909, AND EACH BEARING THAT DATE**

[See note at end of list about copies of these patents.]

| | |
|---|---|
| Adjustable ventilator, F Terramorse | 944,881 |
| Air currents, means for observing and separating heavy objects from dust laden, D. Fogarty | 944,770 |
| Alloys, making and casting J F Monnot | 944,871 |
| Alloys of alkali earth metals, etc , production of Seward & Von Kugelgen | 944,836 |
| Amusement device, E. C. Beebe | 944,407 |
| Amusement device, C F Mack | 944 462 |
| Angle indicator for portable machinery, universal, W T McPhetridge | 944,810 |
| Annealing box, F E. Meets 944,843, | 944,844 |
| Ant trap, J W Mercer | 944,568 |
| Antifouling composition, O Ellis | 944,420 |
| Apples and such like fruit, apparatus for grading, J Loman | 944,867 |
| Apron, E. L. Henderson | 944,853 |
| Ash pan, gravity slide, J J Ryan | 944 506 |
| Assay furnace, D. H. Tennent | 944,470 |
| Axle and bearing, car wheel, G F Rendall | 944 498 |
| Baling press, J W Bohrer, Jr | 944,838 |
| Barrettes, combs, and the like, die for, M Falk | 944 422 |
| Basket, coal, H G Mitchell | 944 807 |
| Bath cabinet, A B. Renehan | 944 911 |
| Bath device, spray or needle, W E. Holmes | 944,611 |
| Bathing suit, buoyant P J Griffin | 944,788 |
| Bearing, ball H Hess | 944,[illegible] |

| [illegible] | [illegible] |

**MECHANICAL BOWLING MACHINE.**

(*Concluded from page 24.*)

trifugal force affected by the band, causes the ball to swerve during its flight. In this operation, though the hand is revolved, the drum upon which the ball rests in the palm or cup is stationary. This device is brought into action when it is desired to give the ball a "spin." There is a groove in the drum in the palm over which a band is passed, and which by suitable arrangements is carried to the same points as the "swerve" pulleys. For imparting a pure spin to the ball, the pulley rotating the hand as above described is thrown out of action, and simply the drum in the palm upon which the ball rests revolves during the travel of the arm on an axis parallel with the drum and at right angles to the line of flight instead of revolving on an axis parallel with the line of flight, as in the action to produce swerve. If desired, both actions can be brought into use at the same time, and then the ball is given a compound or refractory gyration—a combination of swerve and spin—which delivery puzzles the most accomplished batsman because of the erratic and constantly varying rotary axis of the ball.

The device is aptly suited for practising purposes. The velocity of the ball can be altered at will, and there is a "velocimeter" mounted on the machine to indicate the exact momentum during flight. The variations possible are very extensive, and no two successive balls need be delivered alike, the change being effected without the batsman being aware of the fact, or if desired a certain type of delivery can be repeated *ad lib* Every gyration can be adjusted as desired, and indeed it is possible to mechanically reproduce the deliveries of any particular bowler The "break," i. e., the tangent to right or left produced when the ball strikes the ground, is measured by a graduated sight, which also indicates the swerve of the ball to one side or the other during flight Similarly, the ball can be made to leave the "hand" at any point of the arm's travel, there being a series of stops to secure this end In this manner the pitch of the ball, that is the distance from the machine to the point where it comes into contact with the ground, can be easily varied, and similarly the ball can be made to strike the ground in such a way that after the impact it shoots forward at great speed

The machine is mounted on telescopic legs, and the height of the delivery of the ball can be made to coincide with that of any bowler whom it is desired possibly to imitate, the variable range being from six to eight feet above the ground. The mechanism is also arranged to swivel on its body, so that the bowling arm can be pointed in any direction without moving the body The arm is brought to the horizontal position by means of a lever, by which it is also trained and released, and at the same time a disk is raised to warn the batsman of the impending delivery Every ball delivered is moreover registered automatically upon a dial.

**AUTOMATIC RAILWAY SAFETY STOP.**

(*Continued from page 25.*)

duced the locking wedge into its normal position.

The remarkable safety of this apparatus is mainly based on the considerations (1) The locomotive personnel is warned in a triple manner on a closed signal being passed over, viz., (1) by a siren (2) by a warning disk, and (3) by the brake being actuated. (2) The train is stopped: (1) By ordinary braking (in the case of preliminary signals), (2) by high-speed braking (in the case of main signals with two pairs of contacts). (3) The question as to whether the locomotive personnel are guilty, will be fully indicated by the dash and dot records. (4) The track contacts which are only 2.2 kilogrammes in weight, are extremely easy to transport and are readily installed and

(*Concluded on page 36.*)

HOW TO MAKE AN ELECTRICAL Furnace for Amateur's Use.—The utilization of 110 volt electric circuits for small furnace work. By N Monroe Hopkins. This valuable article is accompanied by detailed working drawings on a large scale, and the furnace can be made by any amateur who is versed in the use of tools. This article is contained in SCIENTIFIC AMERICAN SUPPLEMENT, No. 1182. Price 10 cents. For sale by MUNN & Co., Inc., 361 Broadway, New York City, or by any bookseller or newsdealer

ELECTRO MOTOR SIMPLE, HOW TO make.—By G M. Hopkins. Description of a small electric motor devised and constructed with a view to assisting amateurs to make a motor which might be driven with advantage by a current derived from a battery and which would have sufficient power to operate a foot lathe or any machine requiring not over one man power. With 11 figures. Contained in SCIENTIFIC AMERICAN SUPPLEMENT, No. 641. Price 10 cents. To be had at this office and from all newsdealers.

any fish-plate in order efficiently to protect any trains stopped on the track, etc. (6) The fact of the apparatus being disabled by breakage of the lever is automatically signaled to the engine driver by the disk bearing the inscription "apparatus out of working." Moreover, a specially ingenious construction enables the apparatus even then to work as usual on passing over the next signal.

The working condition of the apparatus can be ascertained at any time simply by throwing the lever back and then disengaging the apparatus. The safety stop above described is constructed by the Gesellschaft für Zugsicherung und Patente der Stahl- und Eisenindustrie, of Berlin.

## GRAPHITE MINING IN CEYLON.

(Continued from page 29.)

not be determined without further examination. Much smaller quantities of graphite occur as flakes in many of the granulites and in the crystalline limestones, when it invariably forms small tabular six-sided crystals with well-developed basal cleavage. In these cases, according to Dr. A. K. Coomaraswamy, the director of the Mineralogical Survey, the graphite behaves like the other accessory minerals, and there is no reason to suppose that it has been subsequently introduced.

Evidently the graphite in the veins has been deposited at a time posterior to the consolidation of the granulites, and they are of the most typical character. Usually they consist of pure graphite with occasional evidences of more than one period of deposition in a zoned structure of the vein. Metamorphism of the surrounding rocks near the veins is found on only a small scale, the rock surfaces in immediate contact with graphite being impregnated with the carbon no more than about half an inch. Neither are the quartz and other minerals associated with the graphite vein filled with disseminated graphite, the latter occurring only in strings filling cavities or cracks in the quartz. It is evident that the deposition of the graphite must have been from vapors or liquids saturated with mineral (carboniferous) matter.

The best producing districts are Kegalla, Ruanwella, and Pasdum, but areas are found over the island with the exception of the northern and eastern portions. The mining is almost exclusively in the hands of the natives, and primitive methods obtain. There are but little organized means of prospecting. A villager stumbling across evidences of graphite immediately completes arrangements for working it. A pit is sunk until the vein or deposit is gained, and the mineral extracted until the yield fails. When walking through plumbago areas, numerous abandoned shallow pits may be seen alongside the roads.

In the richer districts more methodical working is adopted, but even here there is a quaint antiquity about the mining equipment. The pit rather resembles a fissure in the rocks than a symmetrical excavated shaft. At the top a heavy staging or platform is erected, from which extends downward to the working levels a crude ladder fashioned from lengths of bamboo secured together to form a continuous run with coir or native made jungle rope. The transverse sections forming the steps are likewise made from pieces of bamboo similarly secured to the side members and spaced somewhat widely apart.

In many instances the ladder comprises sticks of bamboo expanding across the width of the fissure and imbedded in the earth on either side ranged at a slight angle, so as to give the impression of an inclined flight of steps. [illegible]

(Continued from page 36)

(Continued from page 36)

with the mineral which under the friction of the bare foot has a most brilliant polish and is dangerously slippery except to the active movements of the miner

The graphite is excavated by quaint crude tools and instead of being hoisted to the pit mouth by rope and pulley is loaded into tall baskets of native manufacture resembling small barrels loaded on the shoulders of the native who carries it bodily up the long ladder to the pit mouth As a result in a busy pit there is a constant endless train of ascending and descending natives bearing their baskets swarming up and down like flies their bodies covered with plumbago brightly polished giving them the appearance in the sunlight of moving figures wrought in bright steel

Should the pit become flooded a simple system is adopted A rude conduit formed of lengths of wood placed diagonally together so as to afford a V channel is improvised which leads to a lower level a small orifice being bored through the side of the pit if necessary to secure the outlet The water is baled out by natives equipped with small vessels

At one or two of the pits where the veins are abnormally thick some pretense to modern mining methods is made The water is removed by the aid of steam pumps and the native ariters are displaced by power hoisting plants hauling the mineral from a depth of four or five hundred feet to the surface At Pelawatta the most extensive workings in the Pasdun korale such an installation has been laid down and here the prevailing conditions warrant the outlay for such machinery since one main vein striking north and south has a maximum thickness of twelve inches

Owing to the heavy demand for graphite that ensued as a result of the South African war when $31 per ton was realized a plumbago fever broke out among the natives Such a price induced individual working and illicit mining on crown lands Even to-day the latter traffic takes place Should the mineral be proved to exist on the government property licenses are daily issued by the authorities to respectable individuals to exploit the deposits but the natives resort to poaching

The graphite as it is mined is taken to the cleaning and grading works It is first submitted to a preliminary hand selection all the large pieces which are for the most part pure graphite or are associated with pyrites and selenite being placed on one side The sieves comprise screens of varying mesh stretched on wooden frames inclined at an angle over which the mineral is emptied from small shallow baskets and then rubbed by hand the larger or coarser pieces falling to the base of the screen while the minute particles pass through the meshes This process is repeated several times work being commenced first on the small est meshed screens In this manner the dust and much of the friable loose earth is separated This phase of the work is carried out by women and children

Sifting completed the graphite then undergoes cleaning The product being brought in from various localities may be found associated with other matter such as ironstone or carbonaceous deposits of various descriptions and this deleterious material is removed by hand This operation also serves to separate the mineral into two qualities the market price of which averages from $175 to $200 per ton for the first and from $[illegible]0 to $125 per ton for the second grade

The industry has attained great prosperity upward of 30 000 natives being employed in the mining of the article the value of which production considerably exceeds $5 000 000 per annum The industry is also for the greater part in the hands of the natives many of whom have amassed considerable fortunes since owing to the cheapness of the labor, ample supplies of which are readily avail-

(Concluded on page 39)

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES

Inquiry No. 8918.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres. The Nat'l Co-Op. Real Estate Co., Suite 3[illegible], Marden Building, Washington, D. C.

## HELP WANTED

STEAM SHOVEL DESIGNER.—Wanted man with wide experience in their design and construction. Address, stating experience, Designer, Box 773, N. Y.

Inquiry No. 8990. For information regarding shoes not made of leather but similar to the same and are as durable.

## FOR SALE

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads, 3 to 40 in. Price only $40.00. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 8997. Wanted, the manufacturers of the Van Winkle Woods & Sons, and the Weber power meters.

FOR SALE something new, the Brown Mattress Handles, saves lifting the old way. The patentee has no funds to promote it. Reasonable royalty terms will be made with right party or will sell outright. Mrs. W. M. Brown, 125 North 1st Street, Raton, New Mexico.

Inquiry No. 9014.—For manufacturers of machinery, supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

## LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9019.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9023. Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

Inquiry No. 9025.—Wanted, address of rubber manufacturers in Germany.

Inquiry No. 9039. Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

Inquiry No. 9036. Wanted, the address of the manufacturers of "Cycle Ball Bearing Suspenders."

Inquiry No. 9038.—Wanted, the address of the Chipman Electric Purifying Co.

Inquiry No. 9043. Wanted the address of Farney Safety Razor Co.

Inquiry No. 9041. Wanted to buy outfits necessary for agate polishing.

Inquiry No. 9046. Wanted, machinery used for the manufacture of all kinds of fruit boxes, baskets and crates.

Inquiry No. 9048. Wanted, address of manufacturers of metal table slides for extension tables.

Inquiry No. 9049. Wanted to buy rotary brushes suitable for a shoe shining machine.

Inquiry No. 9050. Wanted to buy machinery, etc., for a beer plant, that manufactures beer by means of glucose.

Inquiry No. 9052.—Wanted address of firms who install plants to manufacture nitrogen.

Inquiry No. 9051.—Wanted address of manufacturers of articles made from mica.

Inquiry No. 9053. Wanted address of parties interested in Log Cleaning Machines.

Inquiry No. 9056.—For manufacturers of window shades.

Inquiry No. 9057. For manufacturers of glass and china balls used as fixtures or ornaments on lightning rod equipment, also weather vanes for same purpose.

Inquiry No. 9058.—Wanted firms who make machinery used for pulverizing soapstone.

Inquiry No. 9059.—For manufacturers of flexible steel chain mail.

Inquiry No. 9060. Wanted to buy machinery to manufacture seed corn racks.

Inquiry No. 9061.—Wanted the address of manufacturers of auto magnetos and permanent magnetos.

Inquiry No. 9062. Wanted to buy a plant for manufacturing muriatic acid.

Inquiry No. 9063.—Wanted to buy a machine that would wrap and tie up a loaf of bread.

Inquiry No. 9064.—For manufacturers of a cigarette making machine constructed as follows, a small metal box containing tobacco and papers, the cover contains a piece of cloth upon which is placed the paper and tobacco, the cover being closed the cigarette jumps forth.

Inquiry No. 9065.—Wanted to buy a second hand telephone generator.

Inquiry No. 9066. Wanted complete outfit for export for making rice-flakes and wheat-flakes.

Inquiry No. 9067.—Wanted the address of makers of the Standard Folding Typewriter.

Inquiry No. 9068. Wanted to buy machinery for manufacturing chewing gum, such as rolling, cutting or wrapping machinery.

RUBBER STAMP MAKING.—THIS article describes a simple method of making rubber stamps with inexpensive apparatus. A thoroughly practical article written by an amateur who has had experience in rubber stamp making. One illustration. Contained in SUPPLEMENT 1110. Price 10 cents. For sale by Munn & Co., Inc., and all newsdealers.

able, while the capital outlay is small, a handsome profit is secured. The industry is however somewhat controlled by the government, which levies an export duty of about $2 per ton, representing an annual contribution to the revenues of the island of about $100,000. The increasing extension of crucibles in the metallurgical industries, and the resultant increased demand for graphite is responsible for the present flourishing condition of the industry.

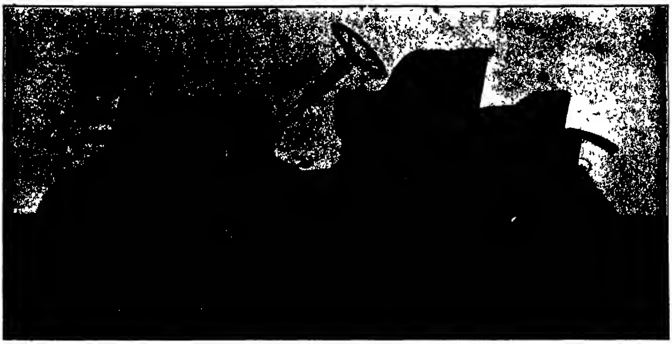
### Woven Aluminium.

Aluminium, as is well known is extracted from clay and it was Napoleon who styled it the "silver of clay." Formerly it was the practice to extract it from the clay with the aid of retorts. More recently the electrical current is employed for this purpose with marked success, the cost of producing this valuable and by no means fully utilized metal, having by its employment been very much reduced. In 1850 a pound of aluminium cost about $40; nowadays it costs only about 20 cents. Above all other metals, aluminium has the greatest specific lightness with the greatest durability and toughness. It can be rolled, cut and drawn exceedingly fine. This has made aluminium valuable and useful in the textile industries. For many years, woven sieves or screens have been made of aluminium, which have proved indispensable in the sugar refining industry. Its principal advantage consists in the fact that the surface of the aluminium, on the slightest exposure to the air becomes covered with a coating of oxide which is capable of offering almost perfect resistance to foreign influences such as acids, etc. This is likewise of great importance where aluminium is used in the textile industries.

Speaking of actual weaving of aluminium into special fabrics, particularly such as are intended for use for decorative purposes and costumes, it may be stated that this is well and successfully practised in England. At the time of the Paris exhibition, there were shown as special attractions fabrics and clothes made from glass fibers. They were made from finely spun glass with silk. The fabrics made from aluminium do not need combination with other textile yarns. Of late the most beautiful effects have been obtained by employing aluminium in smooth as well as twisted threads for the warp and as the weft silk yarn of any desired color. They are used for evening cloaks and theatrical costumes. As the Textil Woche says it makes the body of a beautiful woman look as though dipped in silver. From aluminium, they are now making neck cloths, pompadours, shoes, belts, neck ties, shawls and hats, and it is hard to prescribe a limit for the possibilities of this metal. Very striking are net fabrics in combination with aluminium which constitutes a select novelty for interior decoration. Aluminium yarn made up into laces for ladies' shoes as well as used for straps, promises to be a feature of the coming season.

It would be quite an advantage to the motorist, states a contemporary, if he could communicate by wireless telephone with his garage or the nearest repair shop in case of accident. An American inventor who is developing a system of wireless telephony recently made experiments with portable apparatus to determine the range of service of the instrument. He was able to communicate over a short distance with a garage in Newark, but at a distance of eight miles the apparatus failed. Apparently wireless telephony will have to be developed for beyond its present efficiency before it can be of service to the motorist. The chief difficulty is that only a short transmitting antenna can be used, requiring an enormous expenditure of energy to reach a city garage, because of obstacles in the way, such as steel buildings, trees, wires, etc.

# Everyman's Car at Last
# 1910 BRUSH $485.00



RUMBLE SEAT AND TOOL BOX $20.00 EXTRA

## Everyman's Car—

**Merchants**
**Physicians**
**Salesmen**
**Corporations**
**Contractors**
**Farmers**
**Clubmen**
**Suburbanites**

## The Young Folks—

**The Brush knows no class; there is no limit to its usefulness. A tried, proven automobile for less than the cost of a good horse and buggy.**

*MAIL THIS COUPON TODAY*

BRUSH RUNABOUT CO. Sc. Am.
167 Baltimore Ave., Detroit, Mich.

*Please send me copy of the new Brush Catalog.*

*Name* ..................................................

*Address* ..................................................

*City* ..................................................

*State* ..................................................

## Think of it—$485 for the best-built, most thoroughly proven, easiest riding, most economical, handiest small automobile in the world!

The New Brush Runabout not only outclasses all small cars but is far ahead of its own previous high standard.

Even though we have learned the lessons all manufacturers have to learn by experience—even though we have manufacturing facilities as nearly perfect as money and brains can make them—still we could not build a car of the quality of the 1910 Brush if we merely imitated the big cars with all their complicated parts and all parts necessarily smaller and weaker.

Here's where the genius of the designer counts.

The Brush has always been and still is the only real Runabout built in America.

The new 1910 Brush is not a designer's dream but the result of years of experience and a knowledge acquired by manufacturing 3,000 Brushes that are in daily use. It is a car which with one chassis adapts itself perfectly by change of bodies to a hundred different uses.

It is a car new in power, smoothness, speed and looks but built on proven principles by an organization already perfected.

The Brush has the fewest possible parts but they are of sufficient size and strength to stand the hardest knocks.

Simplicity makes it possible to build the car right and still sell it at this wonderful price.

As for reliability there is no comparison between the Brush and any of the small imitations of large multi-cylinder cars.

With the new Brush you get single-cylinder simplicity, reliability, light weight, low gasoline and oil consumption, low tire expense with four-cylinder power and smoothness.

Its new balanced motor runs as quietly as a four-cylinder and is as flexible. Its power is astonishing.

The most wonderful improvement in Motor Car construction in years.

While the balanced motor is the most remarkable feature of the 1910 Brush, we have made numerous other improvements and refinements.

Here are some of them: wheel-base lengthened 6 inches, more graceful and rakish lines, Mercedes type radiator, new selective control, universal coupling-shaft, improved dust-proof commutator, multiple disc low and reverse clutches, transmission control levers entirely housed and oil-tight, more quiet muffler.

In our magnificent new plant we make every part of the Brush except the wheels, tires and electric equipment. The Brush buyer pays no middleman's or parts maker's profit.

### READ THE SPECIFICATIONS

**Motor**—10 H. P., *balanced* single cylinder, four cycle, vertical, 4" x 5" water cooled; located in front under hood; every part instantly accessible; three point suspension.

**Balancing**—After balancing by the usual counter-weights, one extra loaded balance gear, driven by a crankshaft gear, is applied, the result of which is to take out all of the vibration due to reciprocating weight and in addition most (or at times all) of the torque vibration—*theoretically in better balance than a four-cylinder motor.*

**Transmission**—Internal gear type, perfectly quiet; entirely enclosed and absolutely oil-tight.

**Cooling**—Mercedes type radiator on Brisco thermo syphon system, eliminating pump.

**Drive**—Double side chains to rear wheels.

**Control**—Single hand-lever of selective action for all speeds, spark and throttle under steering wheel; foot pedal releases clutch without touching the hand-lever and also applies the brake. This clutch release by the foot is one of the fine features of the Brush and is found on no other low priced car.

**Steering Gear**—Another exceptional feature; internal reducing spur gear slow and powerful at straight ahead and accelerating as the wheel turns; entirely enclosed and oil tight.

**Axles and Frames**—Oil treated, selected wood oak, hickory and maple; wonderful for strength, durability and lightness.

**Springs**—Spiral, located at extreme four corners; absolutely the easiest riding springs on any car and mechanically impossible to break.

**Brakes**—Internal expanding in rear sprocket hubs.

**Wheels**—Artillery, with 28" x 3" pneumatic tires.

**Wheel Base**—80 inches.

**Tread**—56". For Southern trade 60".

**Equipment**—Tools, tire kit, 3 oil lamps, horn.

**Color**—Maroon except coupe.

**Body**—Divided seat, trimmed in high grade leather. Platform on rear, as pictured above with equipment $485.00.

Six special bodies, furnished on order at extra prices, as follows: rear platform with steel tool box, rear compartment with removable steel deck, single or double rumble with wooden tool box, racer type, coupe.

**Speed**—35 miles an hour, except racer type, which has special gearing.

**BRUSH RUNABOUT COMPANY,** 167 BALTIMORE AVENUE, DETROIT, MICHIGAN

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## THE 1910 AUTOMOBILE

CONVINCING evidence that the automobile of to-day is as far perfected as the materials of construction and mechanical ingenuity will allow, is afforded by the fact that the cars shown in the two annual exhibitions this year exhibit no novelties of a radical character as compared with the cars of the preceding year. Indeed, were it not for the relatively short life and high cost of the tires, the automobile would surely be entitled to rank as the most perfect and economical means of transportation of the present day. As to whether some cheaper and more durable substitute, having the same resiliency as rubber, will be found during the immediate future, we can only say that there is not at present, as far as we know, any promise that such a substance will be produced. At the same time, the development of the car has been along lines that are highly favorable to the life of the tire, for both the weight and the horse-power have been greatly reduced. Moreover, the average owner is beginning to understand that the exercise of discretion in the use of the brake, in avoiding rough places on the road and in slowing down at curves, will add from fifty to one hundred per cent to the life of the tires.

The tendency toward standardization is even more marked this year than last, and the freak car is conspicuous by its absence. The predominance of the four-cylinder motor would indicate that this is to be the prevailing type of the future. The six-cylinder motor is being made, but in spite of its acknowledged advantages of more even torque, etc., it is mainly confined to expensive cars of high power. An encouraging feature, based upon thoroughly sound mechanics, is the increased length of stroke, two of the leading makers exhibiting 30-horse-power cars with cylinders 3½ inches by 5 inches stroke and 3¼ inches by 5 inches stroke respectively.

Undoubtedly, the present flood tide of prosperity in the automobile industry is due largely to the fact that a multitude of people of moderate means, who have been waiting until a thoroughly serviceable car embodying the latest improvements was placed on the market at a low price, is now being accommodated. Several makers are offering a four-cylinder 20-horse-power car having all the features of stylish design, accessibility to the parts, and ease and certainty of control, of the more costly designs, for the low price of $750. Cars of this type have proved during the past year that with judicious handling they are perfectly well able to stand up under constant and severe service. For all cars the four-cylinder, four-cycle engine, with variations in the valve arrangements to suit the tastes of the various builders, has become the standard type, and the indications are that ultimately the cylinders will be cast *en bloc*. Crankshaft ball bearings have given place to babbitt parallel bearings of liberal area, although a few first class makers are using a modified ball bearing with an outer rotating ring. For axles, although a few still use the balls, the roller bearing seems to be established as the standard practice.

There is a practically universal use of high-tension ignition. All machines down to the lowest priced, use magnetos with either a four-cylinder coil and timer as auxiliary or a dual system of ignition. The shaft drive is in almost exclusive use, the chain being retained only on very large cars. The transmission, except on the smallest cars, is almost invariably of the sliding and selective type, with three speeds ahead and one reverse, and the excellent results obtained by those firms which have placed the transmission on the rear axle are bringing this arrangement into general favor.

Lubrication is effected mainly by two systems, one employing "splash" lubrication, in which the cranks pass through a bath of oil contained in the bottom of the crank case, and the other employing a trough and a pump, which causes a constant and positive circulation through every bearing. Outside of a tendency to enlarge the size there are no notable changes in the valve mechanism of American cars, and it is rather remarkable that, in spite of the increased use which is being made abroad of the slide valve (a distinctly American invention), there seems to be no disposition to develop this type in the land of its birth.

Although the multiple-disk clutch bids fair to become the exclusive type abroad, the familiar, leather-covered cone clutch has rendered such excellent service on American machines that it still holds its own, and this in spite of the fact that the multiple-disk type has been giving good results on such American cars as carry them.

In the manufacture of car bodies, there is a marked tendency toward the adoption of straight line designs. Several stylish-looking cars, both of medium and high power, are shown with the much-talked-of torpedo body, in which both the front and rear seats are entirely inclosed, the cars being provided with side doors, forward as well as behind. The provision of doors that open toward the front instead of toward the rear is commendable, both from the standpoint of convenience and safety. An additional advantage of the torpedo body is that it provides excellent protection against the rush of air, particularly on high-speed cars. A notable tendency of the times is the growing popularity of wind shields and "tops," the appreciation of the former being due largely to the general objection to wearing goggles. The use of tops renders the motorist comparatively independent of the weather, and they unquestionably add to the all-round comfort of touring.

The question of the relative advantages of the right-hand and left hand drive is coming to the front, and some makers are offering cars with steering wheel placed at the left of the car. Unquestionably the right hand position is preferable in those foreign countries where the rule of the road in meeting and passing is the opposite of our own. There, in meeting a car one passes to the left, and the driver, if seated on the right of the car, is in a favorable position for judging of the necessary clearance. In this country, where the rule of the road is reversed, it would seem logical also to reverse also the position of the driver.

The handsome display of motor trucks forms perhaps the most notable feature of this year's exhibition, no less than seventeen different makes of commercial motor vehicles being shown at the Grand Central Palace. In quality of design and workmanship, and in the variety of uses for which the vehicles have been built, this section compared favorably with the best work shown in the other automobile exhibits, and as one passed from one to another of those powerful machines and noted the excellent combination of compactness and great capacity the impression became strong that at length after many years of discouragement, the motor vehicle had come into its own. Certainly the statistics of the trade bear out this conviction, for it is estimated that during the coming year about fifty thousand commercial vehicles will be built in this country alone. This gratifying result is the outcome of several years of careful experimental work, in which wholesale houses, department stores, express companies, and the big brewing concerns have been trying out various designs of vehicles under widely different conditions of traffic, both in summer and winter. That the manufacturers themselves have faith in the future of the industry is proved by the fact that, in several cases, they are considerably enlarging their plants to meet an expected increase in the demand, and one firm alone in the West, is to-day in a position to turn out five thousand motor vehicles for commercial use during the present year.

## IMPROVED QUALITY VERSUS PRICE REDUCTION

FIVE years ago or more, when a man paid $3,000 or $2,500 for a touring car, or $650 to $1,200 for a runabout, he scarcely expected to get much in the way of reliability and durability—or, if he did, in the exuberance of unsophisticated anticipation, he was pretty sure to be disappointed before he had used the car many days. The narrative of an automobile run in those days was usually a recital of a series of troubles of various sorts, chiefly with tires, carbureter, and ignition, but also frequently with breakages and imperfect functioning of valve mechanism, shafts, gears, chains, and even steering knuckles, driving axles, and other vital parts.

Conditions are very different in the present state of automobile development, when it becomes a matter of surprise to even well-posted observers that eight out of thirty cars taking part in the Glidden tour of 1909 should finish an arduous trip of 2,640 miles run between Detroit, Chicago, Minneapolis, St. Louis, Denver, and Kansas City in fifteen days at an average speed of twenty miles an hour during the daylight running periods, without suffering a single involuntary stop for repairs, or for adjustments of any sort on the way except to brakes, carbureter, the ignition system, and tires. Considering the road and weather conditions under which the work was done and the lack of daily inspection, cleaning, and adjusting, this probably represents a higher degree of efficiency and performance than can be shown for any other mechanical construction.

The wonderful improvement in motor-car quality made evident by the results of this test and by a comparison of the specifications of the machines of to-day with those of machines selling at about the same prices in the early part of the decade now drawing to a close, is due to a number of contributing causes, but to none more than to the production and use of special grades of steel, bronze, aluminium, and babbitt having certain definite physical properties suited particularly to the requirements in different parts of the automobile. The manufacture of first-class or even reasonably satisfactory motor cars in this country was practically impossible until the then small group of experimenters and builders were able to convince the metal manufacturers of the large possibilities of the automobile industry, and thereby induce them to undertake the production of nickel steel and chrome nickel steel for use in crankshafts, transmission shafts, driving axles, sliding, differential, and steering gears, steering knuckles, and similar parts, and of manganese bronze, phosphor bronze, and various aluminium alloys for use in crankcases, gear boxes, steering-gear housings and similar parts demanding great stiffness combined with light weight. The automobile industry is very largely responsible for the discovery of the physical properties of chrome-nickel steel and vanadium-chrome steel under different modes of heat treatment, as annealing and oil tempering, and for the introduction of the special tool steels required to work them.

Before the special alloy steels were brought out, the motor-car manufacturers nearly reached the end of their resources in the effort to produce safe, durable cars of satisfactory power and speed without excessive weight. The transformation that has been wrought can be better comprehended when it is shown that it is not uncommon for specially treated chrome-nickel or vanadium-chrome steel to show a tensile strength of more than 200,000 pounds per square inch as compared with 50,000 pounds tensile strength of fibrous iron of a quality used by wagon makers and also employed for certain purposes in automobiles. That is a bar of the alloy steel one inch square is capable of sustaining a load of 100 tons without breaking. The qualities most sought in metals for sliding gears, crankshafts, camshafts, driving and differential pinions and gears and live rear axles are elasticity to resist torsional stresses and impact, hardness to resist wear, and ductility to bend under heavy shock instead of snapping. But ductility must be subordinate to elasticity, as it was found in the earlier days of the industry that the soft Swedish iron and low-carbon Bessemer crucible steel would take a permanent set under the repeated shocks and stresses, and throw the shafts and gears out of alignment.

As a result of the employment of steel of such wonderful strength in the sliding-gear sets, by way of illustration, it is now possible to transmit the 40 and 60 horse-power of the modern touring car with smaller and lighter gear sets than were used in cars of 12, 15, and 20 horse-power five years ago, and that with much greater certainty against breakage and the practical elimination of the mangling of the ends of the teeth by meshing and of wear due to contact under load. By the similar use of special metals in all parts of the machine that must sustain heavy torsional stresses, frequent and heavy impact, or much friction, the designer has been enabled to keep down the weight while constantly increasing the strength and life of the machine as a whole. This accounts for the great speed, power, quick acceleration, perfect manageability, and the dependability and durability of the cars of to-day weighing little if any more than machines of a quarter or third the power and half the speed, built during the first half of the decade.

All this improvement in quality, plus infinitely more grace in general lines and in comfort to the passengers, and a complete equipment of folding top, wind shield, head lights, magneto, and other expensive fittings, is offered to the buyer almost at no advance in cost over the ungainly, uncomfortable, and poorly-equipped cars of six and seven years ago.

The high steam shovel record for August on the Panama Canal excavation was made by a shovel working in the Culebra District, which excavated [illegible] cubic yards of earth in twenty-six working days. A shovel working eight days in the Culebra District and eighteen days in the Empire District excavated [illegible] and 26,518 cubic yards, respectively, a total of [illegible] cubic yards, the second high record for the month. A third shovel in the Culebra District made the high record for one day by excavating [illegible] cubic yards of rock and earth.

## ENGINEERING.

**The Jungfrau railway**, which has formed the subject of illustration in this journal, is making steady progress. About 130 men are engaged on the tunnel between Eismeer station, 10,345 feet, and the Jungfrau Joch, 11,090 feet above the sea level. The present indications are that the road will be completed toward the close of next year.

**At the last meeting** of the American Society of Naval Architects and Marine Engineers, in a paper on "Applications of Electricity to the Propulsion of Naval Vessels," Mr. W. L. R. Emmett estimated the efficiency of the turbo-electric installation at 92 per cent, and he, at least, is of the opinion that no other form of speed reduction between turbine and propeller can be made to show equal efficiency.

**In a recent article** in one of the magazines, Admiral Evans takes a rather pessimistic view of the future of the Panama Canal. He sees but little revenue in prospect, and apparently he holds the view that, unless the canal be declared free to all navigation, it will succeed in attracting but a limited amount of shipping. He seems to be of the opinion that it cannot possibly charge a sufficient toll, at least during the early years of its operation, to pay the heavy fixed and operating charges.

**A prize** of $5,000 has been offered in England for a twenty-four-hour aeroplane motor. In weight the engine must not exceed 245 pounds, and it must develop not less than 35 brake horse-power. The points to be considered in making the award will be weight, fuel consumption, reliability, wear of working parts, security against fire, and minimum air resistance. The conditions are severe, but unquestionably the motor is the weak point in the aeroplane at the present stage of its development.

**Emphatic** testimony to the ability of reinforced concrete to resist earthquake shock is given by the experts who were sent by the Japanese to Messina. The buildings that had been constructed of armored concrete, according to Prof. Amore, proved to be highly resistant, and much significance was attached to the case of two reservoirs of considerable size, one of brick and the other of reinforced concrete. The concrete structure received no injury, whereas the brick reservoir was completely destroyed.

**Recently gathered** steam turbine statistics, referring to the growth of this new type of engine in public favor, show that although the first steamer was equipped with turbines as recently as 1901 there are now sixty-four vessels carrying this equipment, the aggregate horse-power represented being 603,200. It is estimated that because of the lower pressure which can be used with the turbine, no less than 120 tons of weight was saved in the boiler room of the largest of the turbine-propelled liners.

**Statistics** published by the Interstate Commerce Commission show that during two years, out of 152 preventable collisions and derailments, twenty-one of the accidents were due to the failure of the locomotive engineers to observe the signals. Evidently the human element enters largely into the question of the efficiency of block signaling. In view of this fact, it is encouraging to note the steady growth of automatic stop devices which, in case of failure of the engineer to obey a signal, will open the train pipe and set the brakes.

**With a view** to guarding the safety of passengers and preserving the life of rails and rolling stock, the Chicago, Milwaukee, and Puget Sound Railway will refrain from running high-speed trains over the new roadbed until it has had time to become thoroughly compacted and a reasonable amount of stone or gravel ballast has been tamped beneath the ties. It takes some time for embankment and ballast to settle into place, and, apart from the risks of operation, the running of fast heavy trains over new track entails costly work in renewals and upkeep.

**Any one** who was familiar with the appearance of the Niagara Falls before the present power installations were built and opened, can settle the question as to whether the appearance of the falls has been affected, by the simple expedient of going to see for himself. Small though the total amount of water taken for power purposes, in proportion to the total amount passing over the falls, may be, it has been sufficient to cause the shallower portions of the overflow at the edges of the falls to become entirely dry, thereby greatly reducing the total length of the crest line.

**During the last month of 1909**, electric service was inaugurated on the newly electrified portion of the London, Brighton and South Coast Railway, London, the particular portion placed in such service being known as the South London Line, which extends nine miles from Victoria to London Bridge. Formerly the running time of this trip was thirty-six minutes; now it is twenty-five minutes, and trains run at ten-minute intervals. Operation is by the overhead alternating-current trolley, and the motor cars are each fitted with four 150-horse-power single-phase motors.

## ELECTRICAL.

**A recent press** report states that a chain of wireless stations is to be established by the British Admiralty in the Pacific Ocean. High-powered stations will be placed at Sydney, Doubtless Bay, New Zealand, Suva, the capital of the Fiji group, and Ocean Island with medium-powered stations in the New Hebrides and Solomon Islands.

**A new** device for connecting wires has just been put on the market. It consists of a sleeve adapted to fit over the wires, which is filled with a requisite amount of solder. The sleeve is furnished with material which when ignited produces sufficient heat to melt the solder. The wires are then jammed together within the sleeve and firmly soldered in this position. The device requires no torch or soldering iron, as the inflammable material can be ignited with a match. The advantages of such a system of connecting wires will be appreciated by those who have tried to solder joints on overhead lines.

**The voltage** on power transmission lines has been rapidly increasing, and at such a pace as to almost take one's breath away. This development has required a similar advance in the design of transformers capable of taking the high-tension current and reducing it to a lower and more serviceable voltage at the points of distribution. The latest transformers of this type have a capacity of 3,750 kilowatts, and are capable of taking a maximum voltage of 138,500 and reducing it to 12,100. These transformers have been built for the Stanislaus Power Company of California. Each transformer unit weighs about 28 tons complete, stands 17 feet high, and occupies a floor space of 9½ by 5½ feet.

**For the** past three years meat has been cured by electricity in much less time than was required by the old method. The meat is placed in large wooden tanks and covered with the ordinary pickle. An alternating current of 35 amperes at 35 volts is passed through the vat, the alternations serving to prevent electrochemical action. Carbon electrodes are used, which are surrounded by porous cups that dip into the brine. The cost of curing a vat full of meat (four thousand pounds) is less than one dollar. The action of the current is not perfectly understood, but it appears to drive the pickle into the meat and hasten the cure. It also appears to preserve the pickle and prevent its deterioration, except for the loss of ingredients taken up by the meat.

**According** to La Lumière Electrique a new microphone has been constructed by Messrs. Carl Egner and J. Kannar, of Holmstroem, Sweden, which will withstand a current of ten to fifteen amperes. The details of the instrument are not given out, owing to the fact that it has not yet been protected by patents. The Swedish government recently connected several telephone lines, forming a line nearly nineteen hundred miles long, and the microphone transmitted speech very clearly over this circuit, whereas with the ordinary apparatus no audible sounds were produced. The new transmitter is being used in the Poulsen wireless telephone system, and it is claimed that conversation has been carried on over a distance of 175 miles, using a high frequency current of six amperes.

**The Navy Department** is giving its earnest support to the bill introduced by Mr. Roberts, who is a member of the House Committee on Naval Affairs, to control amateur wireless telegraphy. Mr. Roberts's measure calls for a board consisting of seven members, one expert each from the Navy, War, and Treasury departments, three experts representing commercial wireless telegraph and telephone interests, and one scientist who is well versed in wireless telegraphy and telephony. It is proposed that the operations of the amateur telegraphers be confined to certain hours of the day, and that each operator be required to take out a license. The Navy Department has recently forwarded to Mr. Roberts extracts from the logs of revenue cutters, showing some of the difficulties with which naval wireless operators have to contend.

**With characteristic** thoroughness the Prussian Government Railways have been investigating the best roadbeds for their lines, also the best trolley systems and motors. About 20 miles from Berlin is an oval shaped experimental railway of about a mile in length. Part of the roadbed consists of wooden ties, and another part of metal ties. Various kinds of ballast are used, and various methods of connecting the rails and ties. Over this experimental railway an electric train is operated every weekday for about twenty hours of the day, and in this way it is possible to determine which form of roadbed will best stand the wear of actual service. The overhead system has been changed from time to time, and different forms of collectors have been used. At present the locomotive on this line is being driven by Winter-Eichberg single-phase motors geared to the wheels. The company expects soon to use motors mounted on the floor of the locomotive, and crank-connected to the driving wheels.

## SCIENCE.

**A moving** picture operator was taken up by Latham recently on a seven-minute trip, at an elevation of eighty feet from the ground. He took pictures with the lens pointing downward. The apparatus weighed 200 pounds, and its operator 196.

**There** seems to be some evidence that pulsatory oscillations of the earth's crust increase where there is a strong barometric gradient, without any relation to the wind. The phenomenon has been investigated by two Japanese scientists, one of whom, Omori, has shown that the earth's pulsations are due to changes in the pressure upon the earth's crust caused by barometric changes or by accompanying changes in the sea level, but not due to the wind itself. Shimono, the other Japanese, has carried on Omori's observations and made a special study of the case of August 4th-7th, 1909, when a depression approached Osaka from the south, finally passing off to the northeast. He obtained records of pulsations with components of 0.06 and 0.07. Other cases also support Omori's view.

**The blanket** effect of clouds, their power of conserving terrestrial temperatures, is discussed by Mr. W. W. Coblentz in a recent number of the Monthly Weather Review. He says that this blanket effect of clouds is due to their high emissivity for radiations emitted by the earth and hence to their high efficiency as heat radiators. A "black body" should have no reflecting power and be opaque. Water reflects only from 2 to 5 per cent of the waves received, and a layer 1 centimeter thick absorbs completely all radiation of wave length greater than 1.5 $\mu$ in the infra-red. The earth's maximum emission lies in the region of 8 $\mu$, and less than 1 millimeter thickness of water is required to produce complete opacity in that region. Owing to this opacity there is little internal reflection of heat waves in the water globule.

**The ironing** of linen may have a greater effect than is expected of it. As the temperature of the iron may greatly exceed 266 deg. F. it has been suggested that the process of ironing may suffice to sterilize surgical dressings and hence be of valuable service, especially in rural districts and elsewhere in the absence of disinfecting ovens and sterilizers. Nearly all microbes can be killed by a sufficiently long application of a temperature of 158 deg. F., but a temperature of 266 deg. F. is required to kill certain spores of bacteria and to produce absolutely complete sterilization. It has been proved by experiment that it is possible to disinfect clothing very satisfactorily by ironing. Clothing which had been worn by children affected by various contagious diseases and which contained bacteria of pus, diphtheria, etc., was sprinkled and ironed. It was then rubbed on plates of gelatine prepared for the culture of bacteria, but not a single colony was developed.

**Prof. Joly** has studied the radio-active properties of the many lavas, especially those of Vesuvius. From his results it appears that the Vesuvian lavas, from 1631 to the present day, are remarkably rich in radium compared with other lavas, the values ranging up to three times the normal for igneous rocks, and sometimes even higher than that. The thorium content, although large in comparison with what generally prevails in the rocks of the St. Gothard series, is not conspicuously higher in the Vesuvian rocks than in the rocks from other volcanoes. The highest reading was obtained from the Krakatao pumice. The Vesuvian lavas appear to show a progressive increase of radioactivity according as they are of more recent eruption, which seems to indicate that, as time progresses, this volcano is tapping materials richer and richer in radium. Prof. Joly has also discussed the possibility of a connection between radio-activity and volcanic activity.

**Not so long ago** Prof. Turner proved that gold leaf becomes transparent when heated in contact with glass. This interesting phenomenon has been further studied by Messrs. J. C. Chapman and H. L. Porter without the use of glass. In their experiments a piece of gold leaf was held by its edges to a platinum loop and heated in a double-walled quartz crucible. As heating continued it was noticed that the gold leaf was becoming more taut, and eventually the tension became so great that the leaf tore in places. Hence at a sufficiently high temperature gold leaf contracts. On examining it microscopically after removal its structure appeared to be decidedly more granular. Subsequent experiments with the leaf hanging like a blind with a weight at the bottom to put it under definite tension showed that as the temperature rose the contraction when it began took place at a great rate with increase in temperature. When different tensions were employed the contraction temperature was nearly the same in all, and was about 340 deg. C. With gold wire instead of leaf no contraction took place. The extra transparency when the leaf is heated in contact with glass is attributed to this contraction, it being shown that the leaf tears on contraction at numerous places, leaving clear intervals between.

# THE MOTOR CAR AND THE ROAD.

## THE DESTRUCTIVE EFFECT OF HIGH SPEED.

BY LOGAN WALLER PAGE,

DIRECTOR OF THE OFFICE OF PUBLIC ROADS, UNITED STATES DEPARTMENT OF AGRICULTURE.

The most serious and difficult problem now engaging the attention of highway engineers all over the world is the preservation of the crushed stone road under the destructive action of motor vehicles, and the devising of new methods of construction adapted to the requirements of this twentieth century traffic. That the automobile has come to stay no one will dispute. It is estimated that there are already about 250,000 machines owned in the United States, and the number is increasing at a marvelous rate. In France, which is credited with having the most superb system of roads in the world, built at a cost of about $625,000,000, a great International Road Congress was sanctioned by the French government and held at Paris in October, 1908. So alarming were the ravages caused by motor traffic on the costly French road system that the purpose of the meeting was announced to be "The Adaptation of Roads to Modern Methods of Locomotion." In the United States, the problem as yet is a vital one only near the great centers of population, for the reason that but a small percentage of the total mileage of roads is improved, and the motor traffic is largely confined to small areas of country, but it will of necessity become increasingly important with the constantly increasing use of the automobile.

The fact that must give us concern is that the old methods of construction which have stood every test for more than a hundred years are inadequate to meet the conditions of this new form of traffic, and that we are in the midst of a transition period which may eventually revolutionize the science and art of the road builder. The highway engineer of to-day is called upon to ascertain in what way the automobile injures the road, what is the exact cause of the injury, and finally to devise an adequate remedy.

When Trésaguet, the great French engineer, made his report to the Council of Bridges and Roads in 1775, he set forth the principles of construction which, as modified and added to by John L. MacAdam in the early part of the nineteenth century, have proven adequate until the twentieth century. These great road builders and their successors sought to secure a road capable of withstanding the wear of iron-tired horse-drawn vehicles, for the motor-driven vehicle had no place in their philosophy. They worked upon the theory that the dust abraded from the crushed stone would fill the voids between the angular fragments and when wet would serve as a cement, thereby making the road surface practically a monolith. The iron-shod horses and the iron-tired wheels passing over the road from time to time were depended upon to wear off a sufficient amount of rock dust to replace that carried away by wind and water, and this, under the action of moisture, recemented, thereby automatically renewing the bond of the road surface. When the road was subjected to drought, the conditions were made normal by regular sprinkling. With the advent of the automobile, a totally new condition prevails. The rubber-tired wheels moving at excessive speed fail to produce any new dust from the rock, but the tremendous shearing effect of the driving wheels forces the loose dust on the road into the air in great clouds, and, as the body of the machine displaces a large volume of air, the deflected currents carry the rock dust off the road, thereby effecting a permanent loss of the all-essential binder. It follows that the road is soon stripped of its fine binding material, and the upper or wearing course of the stone is exposed. These stones, robbed of the binding material, are soon loosened by the great shear of the driving wheels, leaving the road badly raveled or disintegrated. It is, of course, apparent that the effects described are greatly intensified on curves where skidding is most frequent.

Twenty miles an hour.

Thirty miles an hour

Eighty miles an hour.

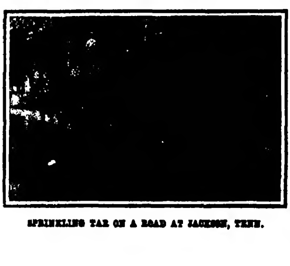
THE DISINTEGRATING EFFECT OF AN AUTOMOBILE TRAVELING ON AN ORDINARY MACADAM ROAD AT DIFFERENT SPEEDS.

Highway and mechanical engineers have given much study to the action of the automobile on the road surface, and many ingenious theories have been advanced. While it is true that the slipping of the tire, the skidding, the shape of the car body, and the suction of the pneumatic tires all contribute to produce the effect, the most conclusive experiments seem to warrant the assertion that the great tractive force or shear exerted by the driving wheels of motor cars is the main factor of injury. A series of tests conducted by the United States Office of Public Roads in 1908 produced some interesting results along this line. Cars of various weights and types were run over a measured course at different rates of speed and right-angle photographs taken of each run. A 60-horse-power car stripped for racing, weighing with driver and mechanician about 2,800 pounds, was driven over a stretch of road first at five miles an hour, each run being increased at the rate of five miles an hour until a speed of 60 miles was attained. Up to 20 miles an hour little or no effect was produced on the road, but from 20 miles an hour the effect was striking with each increase in speed. Little or no effect is produced by the front wheels. Practically the entire disturbance of the road is produced by the rear or driving wheels. If the effect were produced by suction or vacuum, the action of both front and rear wheels should be somewhat similar at least. It seems apparent to the writer, therefore, that the road best adapted to motor traffic is the road which will best resist this powerful tractive shear. It has already been demonstrated that no plain macadam road is capable of resisting this force.

While the destruction of the road may be considered as the most tangible and serious problem, the dust nuisance as intensified by motor traffic is most far-reaching in its indirect effects. It has been claimed that nine-tenths of the dust produced by man comes from streets and highways and someone has very aptly termed the public road the "national dust factory." The effect of the huge clouds of dust upon health must be very great, as most forms of disease are transmitted by this germ-laden dust. The damage to crops growing adjacent to the public highway through the dust nuisance is real and tangible, and particularly is this true of small fruits. So extreme has this condition become in certain districts that no attempt is made to raise fruit near dusty roads. Its effect upon some classes of live stock is most severe, cattle and horses in particular being susceptible to the germs of tuberculosis carried by the dust. The automobile cannot be held responsible for these forms of damage, but it has undoubtedly intensified them. The road builder is, therefore, called upon in many cases to mitigate the dust nuisance by devising a form of treatment which might be considered a palliative.

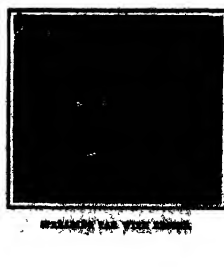
The efforts of progressive highway engineers are directed, therefore, primarily toward the preservation of our stone-surfaced roads and the construction of dustless roads, and secondly to minimizing or mitigating the dust nuisance. The results so far accomplished have been for the most part experimental, and but little attention has been given to the actual composition and characteristics of the materials employed.

It is evident from even the slightest consideration of the subject that the solution of the problem must come, for the most part, from the highway engineer rather than the automobile manufacturer and the legislator. Manufacturers have, to some extent, tried to reduce the dust-raising tendency of their machines by various mechanical devices. Experiments in England brought out the fact that cars fitted with bodies having either very great or very slight clearance raised less dust than those with an average clearance. Some novel devices were tried with more or less success, the



SPRINKLING TAR ON A ROAD AT JACKSON, TENN.

WAGON FOR FORCING BINDER INTO A ROAD.



SPREADING TAR WITH BROOMS.

best results being obtained from a car with a flat steel bottom overlapping the sides of the car, and shoes instead of mud guards. The under screen was six inches from the ground and projected beyond the radiator in front to catch deflected wind from the faces of the car and pass it between the screen and the car, instead of between the car and the road. It is an evident fact that the greater the speed the greater the amount of dust, and the greater the damage to the road. Steps have already been taken to combat the speed mania by the enactment of the most stringent speed regulations. Much difficulty is found, however, in enforcing these regulations.

The experiments conducted by highway engineers, particularly in France, England, and the United States, have been directed toward providing a stone-surfaced road with

CONSTRUCTION OF BITUMINOUS MACADAM ROAD BY PENETRATION OR GROUTING METHOD. HEAVY TAR IS APPLIED ON THE TOP COURSE OF STONE

a binder more powerful than the rock dust. For the purpose of presenting intelligently the experiments thus far conducted with special binders, the term dust preventives' has been applied to all of the various binders having for their object either the suppression or the prevention of dust. These may be divided into two classes, temporary and permanent The temporary binders serve merely as palliatives and require frequent renewal, the permanent binders, so called, enter into the structure of the road as a constituent element, and are either incorporated with the other materials at the time of the construction or applied later by a surface treatment

In the class of temporary binders may be included water, salt solutions, light oils and tars, and oil and tar emulsions, while the

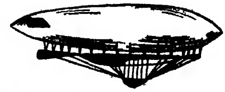
# MOTOR BALLOON GUNS.

## AUTOMOBILE VS. AIRSHIP



It is to their credit that the manufacturers of artillery should so earnestly have grappled with the new problems presented by the development of successful aeroplane and dirigible balloons and so quickly have designed special ordnance to meet the new form of warfare. The firm which has been most active in this direction is the great Krupp Company, in having brought out several types of gun, capable of firing at the high angles which will be necessary in order to hit the rapidly moving airships and planes of the future. Because of the extreme mobility of the new method of attack from the air, it is obviously necessary that the means adopted to resist it shall be capable of a corresponding mobility. This is especially true where the warfare is likely to be carried on against more or less rapidly moving bodies of troops.

Now the automobile because of its speed, weight, and strength, is particularly adapted, not only for carrying light automatic guns but for affording a platform from which they may be fired with a reasonable degree of accuracy. Indeed the artillery motor car armor-plated and carrying a gun that is locked firmly to its chassis, is the natural counterpart of the familiar armored train running on the rails of the regular steam railroad. And although the military automobile will be largely restricted to the roads, and will leave them only under exceptional conditions of smooth and fairly level country, the automobile balloon gun will find a field of usefulness in future campaigns whose limits can only be determined by the hard experiences of a regular campaign.

Of the three rapid-fire-gun motor cars herewith shown, one is American and the other two are of German make. One of our illustrations shows a rapid-fire balloon gun, mounted on an armored motor car of 60 horse-power. The latter, in spite of its weight of three and a quarter tons, is capable of making a speed of 45 kilometers per hour and mounting grades of 22 per cent, even when the roads are of poor quality. The gun is also shown mounted on a semi-armored car. This effective weapon has a muzzle energy of 24.8 meter tons and an extreme range at an angle of 43 degrees of 7,800 meters. At the maximum elevation of the gun, the shell has a maximum height of trajectory of 5,800 meters.

The armoring of the motor cars consists of nickel steel plates, 3 millimeters in thickness, and the gun itself is provided with a special shield capable of a wide arc of aiming. The wheels, also, are covered in with nickel steel plating. The ammunition is carried in a box underneath the back seat, and it will be noted that the front of the car is provided with slits for riflemen.

The guns are provided with shells of a special design, suitable for attacking the gas bag of a dirigible or the canvas or rubber-cloth covered surfaces of an aeroplane. To assist in tracing the flight of the shells, they are furnished, at the base, with a smoke-producing substance which is ignited at the instant of firing the gun, and emits a distinct trail of smoke during the flight of the shell. This gives the gunner some indication of the error in his sighting.

But it will be a very difficult matter to score upon a fast flying machine speeding mile-high above the earth. The most promising form of attack is with shrapnel, which, if burst at the right distance in front of the object, will envelop it in a perfect spray of jagged shell fragments.

Another illustration shows the McClean-Lissack automatic rapid-fire gun, as mounted on a 3-ton Packard truck, for tests which were carried out last year at Cleveland, Ohio. Lieut.-Col. O. W. Lissack, of the Ordnance Department of the United States army, and Dr. S. W. McClean, designer of the gun, had charge of the tests, being assisted by the Standard Automobile Company, the Cleveland dealer for Packard motor cars and trucks.

HEAVY McCLEAN-LISSACK AUTOMATIC GUN MOUNTED ON A PACKARD 3-TON TRUCK.

The gun fired 3-pound shots at the rate of 100 per minute, the range being 3½ miles. Shots were tried with the brakes of the car set, and also released. When the brakes were set the truck did not move, and no shock was felt by those surrounding the gun on the truck platform. With the brakes released there was a slight movement on the recoil, but no shock. The designer of the gun recommends its use on a truck such as the Packard, but armored for war purposes.

We hope to publish additional information regarding the results of additional trials of this gun, which are being made at Sandy Hook and Springfield for the army, and at Indian Head for the navy.

### The Middle West and the Automobile Industry.

BY ALFRED ARNOLD.

Michigan leads all States in motor-car manufacturing, for that State will make 112,000 of the total production of 202,000 cars scheduled for 1910. Four other States adjoining will contribute 70,075 machines. The Middle West may therefore be said to be the real home of the automobile industry. Illinois is scheduled to make 15,300 cars in 1910, Indiana, 21,025 cars, Ohio, 22,750, and Wisconsin, 11,000. In the East, Connecticut will make 2,100 cars, Massachusetts, 4,100 cars, New York, 10,400 cars, Pennsylvania, 3,250 cars, and Rhode Island 800 cars.

These figures are taken from statistics obtainable in connection with eighty of the prominent automobile companies, and are startling to say the least, both as to their bearing on the location of the motor car industry, and on the importance of the automobile industry as a whole. In addition, it must be remembered that there are fifty other firms making 100 cars or less, with 150 makers turning out a few cars or experimenting.

Just why the middle West should lead in motor car manufacture is worthy of some consideration, especially when it is remembered that much of the early experimenting in motor cars and early manufacturing was done at plants in Buffalo and Tarrytown, N. Y., Marion, N. J., Bridgeport and Hartford, Conn., Philadelphia, Pa., and other Eastern States.

Because of the tremendous growth of the industry in the past ten years, and the amount of capital and number of people employed, the settlement of an industry like that of automobile making in any particular section of the country, is a condition worthy of thought. The middle West may be said to be in control of the situation, not alone in the making of cars, but in the making of tires, parts, and accessories. For this condition, we must first give credit to the industrial enterprise of the middle West, for the securing of big factories, for the enterprising methods of its boards of trade, and for the readiness to contribute money toward the securing of new industrial enterprises, like that of motor-car building. Next must be considered the labor situation, which is excellent in the middle West, especially in the matter of hands for automatic machinery. Most of the big machinery making companies are in Ohio or Indiana, where machinists of excellent character are to be had in large numbers.

Besides being the center of the machinery trade, the middle West has been the headquarters for raw material to a very large extent, at least after it has been put through its first or second process, as in the case of rubber, steel, leather, wood, brass, and other things used in the modern motor car.

More important than all is the fact that the middle West is the center for transportation, a most important item when the matter of freight on automobiles is considered. Because of their high value, automobiles contribute very heavily to the railroads, and the matter of freight on incoming material or outgoing cars for an extra thousand miles or so, means an add of cost which every manufacturer tries to avoid. While it is true

# ANTI JOY RIDE DEVICES.

BY HARRY WILKIN PERRY.

So great a proportion of the many fatal or otherwise very serious automobile accidents chronicled almost daily during the motoring season is the result of the use of cars without the owners' knowledge or consent, that it seems as if the time has come when the public welfare demands the general equipment of automobiles with some means whereby the unauthorized use of machines can be positively prevented. If matters continue as they have, it will become incumbent on every law-abiding and gentlemanly owner of an automobile to adopt voluntarily such protective measure, even if laws compelling it are not enacted for the public welfare.

"Joy riding"—as the wild running of a motor car by a partially inebriated driver accompanied by several hilarious companions has come to be called in the automobile vernacular—is of several kinds. It may be indulged in by the lawful owner or rightful user of the machine, by skylarkers passing through the streets and finding an unattended automobile standing by the curb which can be appropriated, and by chauffeurs employed by the owner or by employees of the public garage where the car is kept, who take it out, usually at night, without the owner's or the garage proprietor's knowledge.

Laws have existed for some years in a number of States making it a misdemeanor for anyone to meddle with an automobile standing in the street, and prohibiting users of motor cars from leaving their machines unattended with the engine running. During the past winter there has been much activity in legislative circles for the enactment of laws to prevent "joy riding." The New York Legislature passed a bill containing a provision prohibiting anyone from using or tampering with a motor vehicle without the owner's consent, under penalty of a fine, imprisonment, or deprivation of the right to use the public road for six months, or any or all such penalties. The Colorado Legislature passed a bill to go into effect and be enforced immediately upon its passage, as "in the opinion of the General Assembly an emergency exists," prohibiting any person from tampering with or entering or starting any motor car without the knowledge and consent of the owner or owners, whether an individual or a corporation, and fixing the penalties for infraction at a fine of not less than $50 nor more than $300 or imprisonment for not less than 30 days nor more than 90 days or both such fine and imprisonment.

Such laws will doubtless have a deterrent effect, but they are difficult of enforcement and are punitive rather than preventive, applying the punishment after the evil has been committed. The abuse of automobiles as distinguished from their proper and most desirable use has reached such serious proportions as to call for the general application of mechanical and automatic means whereby the unauthorized use of a machine can be positively prevented or detected the first time it occurs and the punishment made to follow swiftly upon its commission.

Inventors have wrestled with this problem for several years, and a variety of devices have been put on the market to fulfill the desired ends. The difficulties in the way of producing a device that will act as a certain check on the use of the car and yet enable the chauffeur or the mechanic to clean and adjust the engine, test the ignition and generally keep the car "tuned up" to maximum working efficiency are numerous and complex. Chauffeurs and machinists are clever and resourceful or they are unworthy of their hire. A nail, screw, or piece of wire can be made often to take the place of a removable switch plug or the star wheel or spur gear that drives the flexible shaft of a recording instrument can be disconnected. Again, if any operating part of the motor car is positively locked against action, such as the wheels, steering gear, or transmission, it may be difficult to move the machine about in the garage, as frequently becomes necessary for washing, repairing, or in event of a fire when all the cars have to be hurriedly pushed into the street.

Mechanical devices that have been invented with the object of affording partial or complete protection to the owner against the unauthorized use or over speeding of his car may be divided into groups as follows:

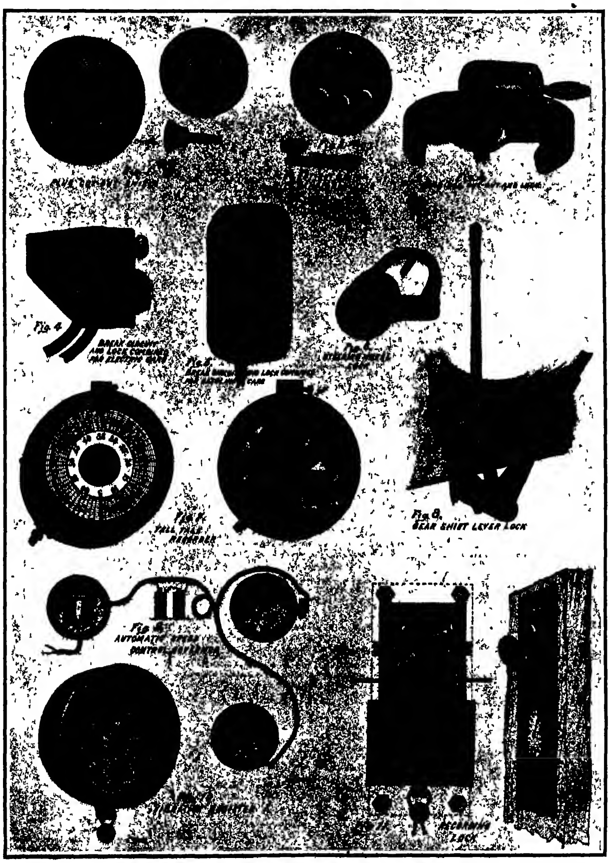
1 Devices to prevent the engine from being started when the car is left standing in the street, embracing (A) ignition switches with removable contact plugs (B) ignition switches that can be locked in inoperative position.

2 Devices to lock essential operative parts, embracing (A) steering wheel lock and (B) speed change lever lock.

3 Speed limiting devices, embracing (A) instruments interconnected with a speedometer and the spark or throttle control so that a given speed cannot be exceeded, (B) audible signals sounded automatically when a predetermined speed is attained, and (C) speed indicating devices with large dials prominently placed so that they can be read at a distance by policemen and others.

4 Vehicle movement recording devices, embracing (A) vibration recording instruments of the pedometer type, and (B) clockwork registers in which permanent records of the time, extent and rate of movement are

(continued on page 58)



ANTI JOY RIDE DEVICES.

# WHAT THE MOTOR VEHICLE IS DOING FOR THE FARMER.

BY WALTER LANGFORD.

Less than five years ago farmers generally looked upon the automobile with bitterness and condemned it as a "toy of the rich." To-day, there are farms comprising hundreds and even thousands of acres, on which nearly all of the heaviest work is done by motor vehicles. There is hardly any part of farm work that cannot be done more quickly and with greater satisfaction by the use of motor power—either applied to a self moving machine or in the stationary form—than with horseflesh. Whether it is making a quick trip to town with a load of butter, eggs, fruit, or vegetables, to the creamery with the evening's cans of fresh milk, to church with the family on Sabbath morning, doing the spring and fall plowing, cultivating, reaping, threshing—the motor vehicle in its varied forms has become the latest ally of the progressive prosperous farmer.

It has been a matter of general knowledge and common comment in automobile circles that extraordinary numbers of motor cars have been going into the remote sections of Kansas, Nebraska, Minnesota, the Dakotas, Colorado, and even Montana, Oklahoma, and Texas during the past season. The statement has been made by a man identified with the trade and presumed to be posted that fully one-quarter of the purchases of motor cars west of the Mississippi during the season of 1909 were made by farmers, and this means a good many when the combined output of the manufacturers of the country for the year aggregated in the neighborhood of 75,000 machines. Some of the little communities in the Middle West, with a population numbering only hundreds or at most a few thousand inhabitants have begun to boast of possessing more motor cars in proportion to population than any other city or town in the country, and to prove it, they congregate all the cars in the village in Main Street and have a group photograph taken.

The farmer, who has long distances to go for everything, from a keg of nails to a paper of tobacco, and who works early and late to make up time lost partly in going "to town," has not been slow to appreciate the luxury and time-saving ability of the motor car. He balances off the cost of a tenth or a twentieth of a gallon of gasoline per mile traveled against a third or half bushel of oats a day at 65 cents a bushel, whether the horse is working or is standing in the stall on a rainy or a winter day, and reckons the time saved to himself as mainly pure gain.

M'INTYRE HIGH-WHEELED MOTOR WAGON CARRYING A LOAD OF FARM PRODUCE.

CARRYING CRATED CHICKENS AND EGGS TO MARKET.

Scattered all the way from the Atlantic to the Pacific coasts there are small fruit and vegetable growers, dairy farmers and poultry raisers who make a daily practice of carrying light loads of produce to market in the tonneau or on the rear deck of ordinary light touring cars. They can leave the horses to work in the field and can make the trip in a third or quarter of the time formerly consumed, thereby gaining just that much additional time to be devoted to more work or to reading, visiting, attendance at concerts, lectures, etc.

The ordinary four or five-passenger touring car of moderate power and reasonable price is most extensively used by farmers. Some of the accompanying illustrations show how such a car is put to practical uses on the farm with the rear seat removed. This is the general utility automobile of the agricultural sections and is used for a great variety of purposes. With it the farmer drives out to his grain field to superintend the threshing, runs down to the pasture with a reel of wire to repair the fence, runs into town with the horses' collars and harness to have them mended, carries cans of milk to the creamery or crates of live poultry to the express office.

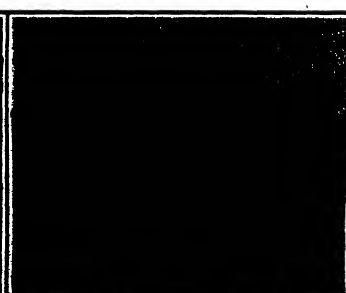
Observing the growing demand by farmers for a car for all-around work a wide-awake automobile manufacturing company in Kenosha, Wis., about two years ago began advertising in the farm papers a double-cylinder light touring car at a moderate price, and inside of a year had sold between 500 and 600 cars in the rural districts. There are now probably between 1,500 and 2,000 of its machines owned by men who live on farms practically all of whom use them as general utility machines. An easily removable tonneau, high clearance above the road, a thoroughly protected engine and transmission, reasonable price and low fuel consumption and maintenance cost have contributed toward making this model popular with the rural buyers. From the statements of hundreds of users, it is found that the average cost of upkeep is not more than two-thirds that of keeping a horse. The farmer of to-day is well informed regarding the mechanical features that adapt an automobile to his requirements and is a careful buyer. He can safely carry 500 pounds on the rear of a 20-horse-power car and can drive ten miles to town in from half to three-quarters of an hour with the load.

Largely as a result also of the farmers' demands there has been developed during the last three or four years a type of motor car called the high-wheeled buggy. There are upward of fifty companies in the country now actively engaged in building this style of motor car especially for use in country districts where the roads are rough, hilly, and, according to the season, deep with mud, sand, or snow. They are very low in price, simple in construction and operation, and answer the purposes of many rural dwellers very well. They use only about a gallon of gasoline to fifteen or twenty miles traveled, and a set of narrow solid tires, costing say $25, will wear a year or more with no expense for repair of punctures or blow-outs.

Within a year or two there has been added to the two-passenger runabout and four-passenger surrey models a high-wheel open-bed light delivery wagon model, of the democrat wagon type, especially suited to farmers' use. A load of 500 to 800 pounds can be carried in the space beneath and back of the front seat, and in some makes an extra double seat can be set in the back to accommodate extra passengers when the vehicle is to be used as a passenger conveyance.

Other light work wagons with open-bed bodies particularly suited for agricultural uses but fitted with longer bodies and having a load capacity of 1,000 pounds or more and costing $1,000 and upward, are

AN AUTOMOBILE TRACTION ENGINE USED FOR DRIVING A THRESHING MACHINE.



A [illegible] HIGH-WHEELED FARM WAGON ON THE [illegible]

TYPES OF AGRICULTURAL AUTOMOBILES.

manufactured by several companies in Chicago, Syracuse, Elgin, Ill., Dowagiac, Mich., and Lititz, Pa. They are excellently suited to carrying to market good sized loads of vegetables, fruit, dairy and barnyard produce weighing from 1,000 to 2,000 pounds, and for hauling back loads of feed, fertilizer, fencing and building materials, farm machinery, and so on The high wheels give the axles and driving mechanism a good road clearance, and the construction is of a heavy and durable as well as simple character.

Numerous cases might be given of motor cars put to special service in connection with farming. In Maryland there is a high-class dairy farm where motor delivery wagons are used altogether to distribute milk among the consumers in the vicinity, and in Indianapolis a large milk company is using a 1½-ton and a 3-ton gasoline truck in the collection of milk from dairy farms within a radius of twenty-five miles of the city, which was formerly shipped by the interurban electric railways or by horse and wagon. In England a large produce grower sends his fresh vegetables to market in a huge motor van, the roof and tailboard of which, as well as the inside, are piled with green goods These examples seem to foreshadow the time, not very distant, perhaps, when farmers will find it cheaper and more convenient to ship all of their farm products to market on motor trucks than to haul them with horses and wagons. Possibly the trucks will be owned by local express companies organized for the purpose, which will charge a reasonable price for haulage, so that it will pay the farmer better to keep his horses—if he needs any then—at work in the field, and he will not need to invest any capital in the motor trucks Doubtless some of the transporting companies will use motor tractors, which will run over regular routes every morning and pick up a string of farm wagons loaded with produce, hauling them to market and back again for a fixed charge A single tractor should be able to haul four or five such wagons over good roads.

In Connecticut a three-ton truck is regularly used for hauling grain and carrying all sorts of farm supplies and products for a 1,300-acre farm This is one of the many fancy estates conducted in the East by wealthy owners largely as a personal hobby yet at the same time as a profitable investment The truck represents an outlay of $5,000 and is kept in a special garage for work motor vehicles which are to be used extensively on the farm

A ranch of several thousand acres in Montana is conducted entirely without horses, the plowing, sowing, cultivating, reaping, threshing, and hauling of the grain to the railroad being done by motor tractors and motor wagons. We have had the horseless street car for twenty years, the "horseless carriage" for ten, and now we have the horseless farm. May we hope some day for the horseless city?

While the foregoing examples are isolated cases and apply to farming on an extensive scale with ample capital, they point to great possibilities for the future use of self-propelled vehicles in farm work, utilizing gasoline, kerosene or denatured alcohol as fuel The farmer with a small acreage who would not be justified in buying a motor tractor for his own use, will be able to hire his plowing and threshing done by companies operating motor tractors, as for many years he has had his threshing done by itinerant steam threshing outfits. And, incidentally, the work will be done cheaper, there will be no danger of fire from flying sparks, there will be little or no water to haul, and there will be fewer men to feed

In this country, as well as in England and France, there are large companies that make a specialty of

AN AVERY FARM TRUCK HAULING SCRAP.

building small farm tractors for universal tractive and stationary power work A company in Minneapolis makes an 8 horse-power tractor weighing 5 500 pounds for such work as operating hay presses corn shellers etc and for drawing wagons and portable machines of this class on the road In York Pa. is another large company that makes motor tractors and traction engines in ten sizes, from 1,000 to 36,000 pounds in weight. The smallest is rated at 1½ to 2 horse-power and is intended for all sorts of farm work such as hauling the stone-boat, churning pumping feed cutting, etc.

American motor tractors used for plowing and threshing usually develop from 12 to 35 horse power and weigh from 5 000 to 20 000 pounds They haul gang plows turning from two to eight furrows at a time One of these—a 15-horse-power tractor built by the largest harvesting machinery company in the world—plowed 1 09 acres of "gumbo soil with a three-furrow 12-inch bottom plow in an hour and a quarter on a consumption of 1½ gallons of gasoline per acre at an international competition held in Winnipeg last July

A "wagon tractor, built in Peoria by a great agricultural implement works for general utility purposes in the field and on the road, was tested at the same trials. Coupled to a two-furrow 14-inch gang plow, it turned over 1 06 acres in 1 hour 25 minutes on a consumption equivalent to 2 36 gallons of gasoline per acre. This would amount to about 50 cents an acre for fuel In a ten-hour day 7½ acres could be plowed for about $3 25, not including labor

This wagon tractor is a very interesting vehicle It was designed particularly for farm purposes by men who are familiar with the peculiar requirements, and combines in one machine a truck for carrying loads on its own body, a tractor for drawing plows and other farm machinery, and a power plant for driving threshing machines hay balers and other stationary machinery by belt It will take the place of several teams and wagons on the farm

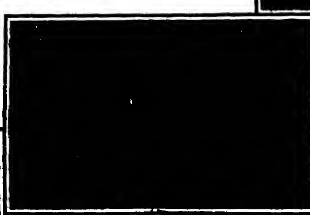
Nowadays, on the farm as well as in the manufactory it is necessary to do the largest amount of work in the shortest time in order to make an undertaking successful This is recognized by the progressive farmer and farm machinery builders and to a large extent the advantages of the motor car and motor tractor are appreciated by builders of farm wagons and buggies Most of the leaders in these fields are now offering their customers a motor buggy, a motor car, a motor wagon, or a motor tractor

### The Modern Electric Automobile.

BY EMIL GRUENFELDT, M.E., E.E.

The heavy cumbersome electric cab or brougham of earlier days has cleared the field for the light runabout victoria or interior driven coupé Less weight means more speed and a greater mileage radius It was looked upon as a great performance when one of the earlier types of electric automobiles traveled forty miles on a single charge of the battery at a comparatively low speed The modern electric automobile will negotiate about twice the distance at a much greater speed The most vital components of an electric automobile are the motor and controller, two parts which are of different design on about every other make For its various advantages the series-wound motor has outclassed its rival of the earlier days, the compound motor The series wound motor, if properly designed will do its work for three hundred and sixty five days in the year without requiring any attention The most desirable motor is not that which tends to drive a car up a hill at a comparatively high speed A heavy battery discharge is thus entailed, which is of course very detrimental to the battery Of two cars traveling at the same speed on the level, that one will travel the faster on a grade whose controller was not changed The motor of this faster

WITH A REEL OF WIRE FENCING AND A BOX OF TOOLS ON THE REAR DECK THE PASTURE FENCE IS QUICKLY REPAIRED.



HALF A DOZEN CANS OF MILK ARE TAKEN TO THE CREAMERY AND THE EMPTY CANS BROUGHT BACK.

car is designed for a smaller increase of torque in proportion to the decrease of the speed Even if this difference in speed is very small say one-half mile an hour the faster car will have to pay dearly for it in current as well as in decrease of mileage radius and in battery wear The good designer will find a middle way He will strive for the highest battery efficiency It is by no means difficult to construct a fast electric, as the power is unlimited for a short distance The art is to apply the power at disposal in the most all-around satisfactory way and to design a carriage which is reliable and cheap to maintain

In the line of various controllers the drum type for good reasons seems to have grown into great favor The various speed changes can be obtained without arcing or burning, and a gradual increase of speed is effected from step to step with a small increase of

# THE MODERN LOW-PRICED CAR.

BY JOSEPH ROGERS.

The automobile buyer faces no such questions in 1910 as confronted him a few years ago, when all that was expected of a car was that it would run. At that time the gasoline engine was not understood as the engineer understands it to-day and all of the parts and appurtenances were undergoing a process of evolution that resulted in vast differences between the models of two successive years. Each make had some peculiarity of design, and the selection of a car was complicated by the difficulty of getting definite information on performance.

There were reliable cars, of course, but their initial cost and the expense of operation made their ownership possible only to the very well-to-do. The car that could be bought by the man of moderate income required close attention and the adjustments and repairs that were a constant necessity left him little time for anything else. If these were in the hands of a repair man the monthly bills were out of all proportion to the mileage covered and the pleasure obtained. Automobiling at that time was unquestionably a diversion for the rich, and it is popularly supposed that such is still the case, but as a matter of fact, the man of moderate income can to-day purchase and use a car at an expense that is well within the bounds of reason.

The primary cause for this is found in the relatively close understanding of engine and car design that obtains to-day. The systematic experimental work that has been carried on in the large factories has resulted in a refinement in design and an approach to a standard that place automobile manufacturing on as economical a basis as is possible in the production of any other mechanism.

The moderate price at which an automobile may be bought is not due to the use of poor material and cheap labor, on the contrary, the low-priced car of to-day is better in quality than the highest grade cars of six years ago.

In the early days of the automobile industry the manufacturer was under the necessity of making all of the parts, to-day, the factories actually making even 75 per cent of the parts that they use are in small proportion to the number of producers. A few years ago, when a manufacturer purchased his engines, change speed gears or other parts, he concealed the fact, to-day, a constantly increasing number of firms make it no secret that their cars are assembled in whole or in part. It is to these changes in policy that the excellence of the medium priced automobile is largely due.

The manufacturer of a complete car is under the necessity of maintaining an experimental department in which he can try out suggested improvements on all parts of the chassis. This is expensive work, and a proportion of the cost of the department must be included in the price of every car sold. The maker of an assembled car is under no such handicap, for each of the firms with which he does business will carry on only such experimental work as is required for its special line, and the expense is borne by so great an output that the individual proportion is negligible.

There was a time when an assembled car was undoubtedly open to suspicion, for however desirous the makers of its parts might be to do good work they had neither the knowledge nor the facilities that would make it possible. These same companies now possess enormous plants, their designers and equipment are the best obtainable, and their products embody the latest and best in practice material and workmanship. Assemblers thus have parts at their command that are of a high degree of excellence, and can buy them at prices that are far below what was charged for the weak and faulty product of former years.

The low prices at which assembled cars can profitably be sold have forced the builders of cars of competing grades to manufacture on a very large scale, in order to bring down costs through economies possible only with quantity production. Such a firm equips its factory with jigs and special tools for every operation, and makes it an inviolable rule to accept no order that calls for even a slight deviation from the standard specifications.

When a manufacturer turns out twenty thousand cars a year, it is not only justifiable but necessary for him to invest very considerable sums in special machinery of all kinds that for a smaller output would be inadvisable. One manufacturer has spent $40,000 for dies to produce a rear axle housing, on a production of one thousand cars, the charge against each for this would be $40. With an output of twenty thousand cars, however, the charge of $2 against each is little enough for the purchaser to pay for so excellent a feature.

A recent development that illustrates the endeavor to reduce manufacturing costs is the establishment by some of the leading producers of assembling shops at the large centers. To these are shipped parts in sufficient quantity to build the cars required for that locality, and as there is no equipment of machine tools, the expense is slight. The freight rate on unassembled parts is much lower than on complete cars, and the saving effected in time and convenience as well as in money makes the system a satisfactory one.

However it may have been in the past the present day manufacturer of moderate-priced cars makes no more than a legitimate profit. One of the largest producers stated recently that his profit on a $1,000 car is less than $100, this is not excessive when one considers his enormous investment in material and parts, his really vast equipment of machine tools, and his labor expense.

It has been said that any average engineer can design a car to sell at $4 000, but that the greatest skill is necessary when the selling price is to be less than $1 000. However that may be, the medium and low priced cars on the market show exceedingly clever designing and bear every indication of the highest grade of mechanical engineering. Being light in weight, the material entering into their construction is selected with the greatest care, and it is typical of the automobile industry that many of the alloy steels in common use were hardly more than laboratory curiosities five years ago.

The whole tendency of design is to reduce weight and machinery and assembling costs, but it is rare to see a case where strength and durability have been sacrificed for economy. One of the features of the 1910 cars is the casting of the four cylinders in one piece, which results in a considerable saving in weight and cost, with no apparent reduction in strength or ability. The increasing tendency to adopt the gravity system of water circulation is another economical move, for it permits the suppression of the pump. The mechanical lubricators that were formerly in general use have been abandoned in favor of a single pump located in the crank case which is not only less expensive to build and assemble, but makes lubrication as positive and unfailing as it well can be. The magneto is now the standard equipment even for cars of very low price, and quite frequently it is the sole means of ignition. An advantage that may be gained through its use is that the spark may be maintained at a fixed point, and therefore the spark control lever and its connections may be done away with. The locating of the clutch and brake pedals on the gear case reduces the cost of assembling, for when they are hung on a rod passing across the frame as was the practice in former years, accurate fitting is an absolute and costly necessity. When the engine, change speed gear and rear axle are separate units, assembling is complicated by the necessity for setting them accurately in line, in a great number of 1910 cars the change speed gear is either built in with the engine or the rear axle, and the cost of assembling is reduced in consequence.

In spite of the excellence of the 1910 cars, it must not be assumed that the limit of perfection has been reached. Some of the work turned out by the designers shows that they have followed a common path, but in many cases there are differences that are not easy to reconcile. The perfected car cannot come until the efficiency of one definite construction has been recognized, and its proper proportions demonstrated. The great variance in the designs of to-day is evidence in itself that there is still much to learn, for otherwise, as an example, there would be less difference in the dimensions of engine bearings than is now noticeable in different makes of engines of the same power. The relation of bore to stroke is the subject of a vast difference of opinion at the present time, and even the relative length of the connecting rod is by no means fixed.

Having produced cars that will run, and that can be depended on for steady service, the problems now before the designer have to do with the increase of efficiency and economy of operation. At the present time it is doubtful if any manufacturer knows what proportion of the power of his engine is absorbed in operating the valves, or in driving the magneto and pump, but these and other far more complicated details must be worked out in his future models.

If the principles of the present engine are adhered to, the coming years will bring a closer and more accurate knowledge of the cycle, and a general adoption of the features and relative dimensions that survive the ordeal of usage. For the car owner this will mean greater economy in the use of fuel, increased simplicity in construction, and the reduction in price that is the invariable result of standardization.

**The Wright Suit and Aviation in America.**

The granting last week by Judge Hazel of a preliminary injunction restraining Glenn Curtiss and the Herring-Curtiss Company from making, selling, or flying their well-known type of biplane has quite taken by surprise almost everyone versed in patent law, as such an injunction has been granted very rarely, if ever, before upon an unadjudicated patent. Even in the case of the Selden patent covering the use of a clutch between the motor and the road wheels of an automobile—a case in which an infringement was much more apparent—such an injunction was not granted. The granting of the injunction at this time has had two results. In the first place it has intimidated a good many inventors who were hard at work upon the perfecting of the aeroplane, and secondly it has encouraged the Wrights to attempt the creation of a monopoly in flying machines. With a million-dollar company back of them, and with orders already booked aggregating more than this figure, the granting of the present injunction gives them practical control of aviation in America. A second step in this direction occurred on January 4th, when aviator Paulhan was served with a notice to appear in the New York District Court ten days later to show cause why he should not be enjoined from flying his Farman biplanes in the United States. As he is booked to make flights at the Los Angeles aviation meeting from the 10th to the 20th, this action may be a serious blow to the first aviation meet held in this country.

The death of Leon Delagrange from a fall sustained as a result of the breaking of a wing of his Bleriot monoplane while flying in a 20-mile wind at Pau, France, on the 4th inst., has given aviation another setback that it will take a long time and many excellent demonstrations to overcome. Four lives lost within the last four months is a record by no means encouraging to sportsmen, and unless everything possible is done to encourage flight in this country, none of the aeroplane factories soon to be started will do much business for some time to come.

**Hydrogen for Inflating Pneumatic Tires.**

The inflation of an automobile tire with a hand pump is so laborious an operation that some automobilists carry cylinders of compressed air, with which a tire can be inflated easily and rapidly. The cylinders, however, may be found empty when they are most needed. Drouetly a French manufacturer of aluminium paper, has conceived the idea of replacing the air by hydrogen, generated by the action of water on specially prepared aluminium waste. In presence of alkalies, aluminium decomposes water into oxygen and hydrogen. The oxygen combines with the aluminium and the hydrogen is set free. The method of operation is very simple. About 10 ounces of granulated aluminium and 10 ounces of water are introduced into an air tube of the capacity (6½ pints) which is commonly furnished by the great tire makers, and the bronze plug is quickly screwed down. In a few seconds the space not otherwise occupied, about 5½ pints, is filled with hydrogen at a pressure of 150 atmospheres. This is equivalent to more than 100 gallons of hydrogen at atmospheric pressure. The other product of the reaction is alumina, which can easily be washed out. The special preparation of the aluminium consists in the addition of a small percentage of mercury bichloride which starts the reaction in the absence of alkalies so that pure water can be employed.

This method possesses two advantages. It allows every automobilist to recharge his air tubes without returning them to the factory. There is also a real advantage in inflating tires with hydrogen instead of air. The diffusion of gases through colloidal substances like India rubber follows a very different law from that which governs the diffusion of gases through porous walls. In the latter case the rate of diffusion is inversely proportional to the square root of the density of the gas, but the rate of diffusion through India rubber is directly proportional to the facility with which the gas can be liquefied. Hydrogen generated by the action of aluminium upon water was used for filling balloons in the Russo-Japanese war, but this ingenious and simple method of obtaining cylinders of compressed hydrogen appears to be as new as it is interesting.

---

To Americans who are accustomed to five-cent car fares, it will be surprising to learn, on the authority of The Engineer, of London, that last month there was inaugurated an electric-car service from one of the London subway (tube) stations to the suburb of North Finchley, on which a fare of half a cent will be charged.

# HOW TO OVERHAUL A CAR.

BY HERBERT L. TOWLE.

In order of importance, the facilities needed for overhauling are a warm, light place to work, an extension electric light, a bench, several boxes for use as receptacles and supports for the dismantled parts, and as liberal an assortment of tools as the owner's means will permit. An iron vise, a bench drill, a foot or power lathe for metal work, and an emery wheel are almost necessary. Failing these, certain parts can be sent to the shop for refitting. A complete kit of bench tools is assumed—hammers, files, hack saw, chisels, wrenches, screwdrivers, cotter pin extractor, etc.; also a soldering torch.

The first step after washing the car is to strip it of lamps, mud guards, and small gear generally. If the screws and nuts are greasy, drop them into a pan of kerosene. Have a large box handy for small parts, and three or four small boxes in it for the purpose of grouping related small parts together. It is very easy to get a car apart and shuffle the various bolts, washers, and other small things so thoroughly that it is impossible to tell where they belong on reassembling.

Ascertain by looking underneath whether the gasoline tank is attached to the body or to the chassis. If the former, disconnect the gasoline pipe at both ends, plug the ends with bits of rag, disconnect the horn tube and any electric wiring that may run from the body to the chassis, take out the bolts holding the body to the side and rear frame members, and lift the body straight up. The dash is a part of the chassis, not of the body, and does not need to be disturbed at this stage. Have a couple of wood horses ready to receive the body. Do not set it on the floor, as there may be parts projecting beneath it, such as the gasoline connection beneath the tank.

The amateur is advised to begin overhauling in the order of ease rather than of magnitude. For this reason the brakes are suggested as a start. Inclosed rear brakes on a car with side chains are generally exposed by taking off the rear wheels. First, see if the brake drums have removable cover plates. If not, take off the sprocket chains, unscrew the hub caps and nuts, and the rear wheels will come off, leaving the expanding brake [illegible] in place and exposed. [illegible] whether or not the [illegible] justment is near its [illegible]. If so, replace the [illegible]. The foot brakes are adjusted or relined in the same way.

Remove the radiator, wash it out under a strong stream of water, and if it is suspected of being encrusted with scale fill it up with kerosene and let it stand—until spring time will do no harm. When reassembling it is important to give the radiator an even bearing around all four studs, supposing it to be held down by that number. If possible, have it rest on ¼-inch sheets of rubber, and do not draw the holding-down bolts entirely tight. The radiator, although frail, is much more rigid than the frame, and any springing of the latter will surely start leaks in the radiator if it has to follow it. The two sketches Figs. 1 and 2, show how a frame may be racked in going over a rough road. If the radiator leaks it is best to let an expert tinsmith repair it (not all tinsmiths are expert). The secret of success is to use a good grade of solder and sweat it thoroughly into the seams, taking plenty of time. If the top is not steadied it will be worth while to run a brace or stay rod to it from the top of the engine or the dashboard. This rod need be only heavy enough to check the vibration.

If there is much lost motion in the worm or other reducing gear of the steering mechanism disconnect the steering links, also the throttle and spark connections, and take the steering column out with the reducing gear at its base. Open the casing and see where the lost motion is. It may be in the threads of the worm *A*, Fig. 3, and the teeth of the segment *B*. Much of it, however, is likely to be in the thrust washers *C C* of the steering column and *D* of the segment shaft. Frequently ball bearings are used at *C C*. In time either these or plain washers need replacement, likewise the bushings *E E*. If the steering gear case is not provided with a grease cup, this is an excellent time to put one in. Wear on the worm and segment *A B* is not easy to take up; an approximate cure is to make the bushings *E* eccentric so that by turning them the centers of the worm and segment are brought closer together. Since, however, most of the wear is in the middle teeth, the gear may be loose in the middle position and tight when the wheels are cramped over. There is no remedy for this, save renewal.

The steering knuckle pivots and the pins in the ends of the cross link wear loose in time, and usually it is a shop job to ream the holes and fit new casehardened pins. See that the front wheels are parallel or "toe in" very slightly when pointing ahead. It is usual to shape the steering knuckles so that the wheels incline toward each other at the ground. They are rarely vertical, and never incline the other way. If the front axle is sprung, have a blacksmith straighten it.

Clean out gear case and test all the bushings, including the pilot bushing at the front end of the squared shaft, by shaking them. If ball or roller bearings are used, replace them if loose; if plain bushings, they must be refitted or replaced. New bushings bought from stock generally need considerable fitting. The rea-

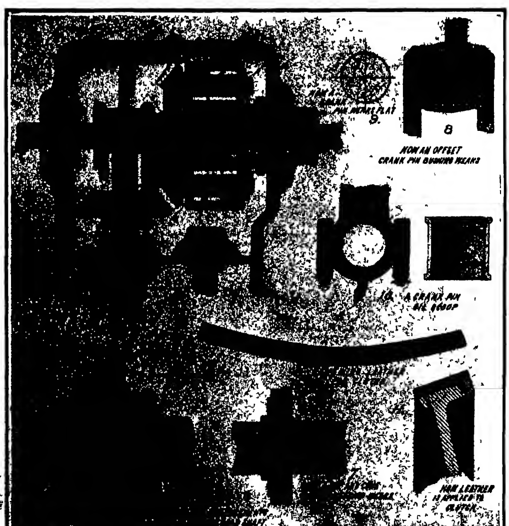
SOME PARTS OF A CAR WHICH MUST BE CAREFULLY CONSIDERED IN OVERHAULING



HOW PARTS WEAR IN AN AUTOMOBILE.

# AUTOMOBILE FIRE ENGINES.

## A NEW TYPE OF MOTOR VEHICLE.

BY HERBERT T. WADE.

The great success of automobile fire apparatus in Europe and in many of the smaller cities of the United States frequently gives rise to the inquiry, why are such machines not used more extensively in the larger fire departments where the highest efficiency of apparatus and personnel is demanded and maintained? The acknowledged utility of automobiles for pleasure and business even under extraordinary conditions emphasizes this tardiness the more forcibly, particularly as the modern motor vehicle is now capable not only of attaining high speed but of carrying heavy loads. Promptness in reaching a fire with suitable apparatus is of prime importance, and the automobile in this respect and in endurance is easily superior to a horse. To-day with high speeds pumping capacity can be secured in a motor vehicle sufficient for most conditions of service, and this, with economy of maintenance after the initial cost, has led to the adoption of automobile fire apparatus by many of the progressive smaller cities. This economy is obviously due to the fact that only when in operation are gasoline and oil required. A horse even when idle entails expense for shoeing and feeding.

Even the most conservative of metropolitan fire officials realize that the rapid transportation by horses and the subsequent operation at high pressure of a heavy steam pumping engine on wheels is more or less a mechanical anachronism in these days, when central power stations have largely taken the place of the small isolated plant, and when small internal combustion motors using gasoline have been found economical, convenient, and efficient. The pumping power of a fire engine depends upon the weight that can be transported. As an internal-combustion motor connected with a pump would weigh much less than a steam engine and boiler and going to a fire would use the same engine for propulsion, it would follow that greater efficiency could be secured. Even superior from the mechanical standpoint, but not as yet practically applied, would be the mounting of an electric pump on a gasoline-driven motor car, using current derived from supply mains near the scene of operation. Chief Binns of the New York Fire Department has developed such an idea which possesses many obvious merits. He proposes to use electrically-driven centrifugal pumps on motor vehicles capable of high speed and to obtain power from electric light standards or other outlets which are at almost every street corner and quite as well distributed as hydrants. The same condition also prevails in many rural districts, where electric light and trolley lines are to be found on every main street. Suitable plugs and conductors could be used for connections, and with the power derived from a central station the portable machinery would be reduced to a minimum weight. A similar idea, though not so elaborately developed, was put into operation more than twenty years ago by Dr. S. S. Wheeler, now president of the Crocker-Wheeler Company, Ampere, N. J. This apparatus consisted of a bipolar motor directly coupled to a pump, and was mounted on a light carriage. The gasoline motor car was not so highly developed at this time, for which reason the carriage was drawn by horses. A fire engine built on this plan was tried out on the Erie Canal at Schenectady. It was finally brought to Ampere, and was destroyed in a fire which occurred there in 1895. Strange to say, this scheme, which would involve comparatively little outlay for a large city, has never been thoroughly and practically tested.

At present, motor apparatus is most widely used in suburbs and small cities with wooden dwellings, in other words, in communities where its high speed renders it possible to cover a much greater territory by a single company, and where infrequent alarms reduce the expense of maintenance far below that entailed for feeding and shoeing horses. For example, a St. Louis motor company recently made a run of nine miles to a country villa outside the city limits and arrived in time to save the house. This same company in a period of eighteen months responded to 1,000 fires without a single failure, and in so doing traveled 2,250 miles in all conditions of weather, including mud, sleet and snow. The economy of this company is apparent from the fact that its maintenance account for twelve months was $481.31, including two accidents, which resulted in an expense of $250, as compared with an annual cost of $816, for feeding and shoeing two horses. Even in a district where there are no water supply hydrants, such a machine can make a speedy run, and draw water from a well, canal, or pond.

MOTOR-DRIVEN CHEMICAL ENGINE.

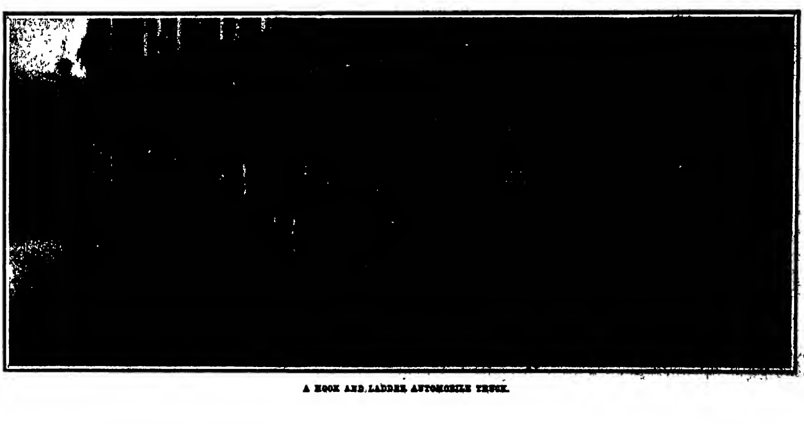
In a large city the question of territory is not as important as that of speed in getting the firemen to the fire. In a district with high pressure fire protection fires occur which taken in time may not require the powerful streams from the fire hydrants and could be put out with a minimum of water damage. Indeed it seems likely that the future fire protection of a large city will consist simply of an efficient high-pressure water system and automobile engines and hose wagons.

In a description of modern automobile fire apparatus we may mention, first, the high-speed touring car or runabout, for the use of chiefs and supervising officials, capable of rapid travel and of covering wide sections of territory. This was the first automobile used by fire departments. Such a car does not usually carry extinguishers or any fire apparatus, one or two small extinguishers and axes or other tools being carried only in rare instances. All that is demanded of such a machine is a high quality and reliable motor car of sufficient speed and easy control. In hardly more than thirty minutes Chief Croker of the New York fire department is at the scene of any fire in Greater New York, directing in person the operations of the firemen. This is significant in view of the large amount of territory comprising the greater city and the dangers involved in some of the outlying districts.

A modification of the chief's car may be seen in that supplied to the battalion chief or the head of the fire department of the smaller city. Extinguishers and tools are often considered essential. The chief carries with him not only a chauffeur but one or two firemen from the permanent headquarters force.

If rapid travel is desirable for the chief, it is of course equally advantageous for the firemen responding to an alarm. In small blazes such as those caused by a curtain blowing against an open gas light or by a short-circuit of a lighting system, one or two men with axes and hooks promptly on the scene can prevent what might be a serious fire in a dwelling house or stable. Accordingly it was early realized that auxiliary or emergency squads could be equipped with motor cars and could be dispatched at high speed to the scene of the fire. These men deal with an incipient fire or prepare for the steam engines which follow and if necessary send in additional alarms or communicate by telephone with headquarters. This type of equipment is extensively used throughout the United States.

But it must be realized that this means simply the prompt bringing to the scene of action the trained men who can take care of the smallest kind of a fire. Without apparatus or sufficient power nothing can be done where the blaze is at all serious. It was with this end in view that automobile fire-fighting facilities were increased by adding a chemical tank and a few hundred feet of small hose. The chemical tank and equipment has now become an indispensable feature of many fire departments. Carried on horse-drawn hose wagon, a small fire can be quenched in its incipiency by its means with a minimum use of water and consequent damage. The chemical tank consists of a copper cistern of from 40 to 70 gallons capacity containing bicarbonate of soda and other chemicals with which sulphuric acid and water may come in



A HOOK AND LADDER AUTOMOBILE TRUCK.

contact to generate carbonic-acid gas at such pressure as to be forced with the water through a small hose This apparatus has been used with considerable success in some fire departments, but it is fair to say has been ignored or found unavailable in others. Especially is this true of New York city, where the practice has always been to concentrate at a fire adequate pumping power at the earliest possible moment and to use large quantities of water the idea being to take no chances and even at the risk of water damage to err on the side of safety

In the horse-drawn combination wagon the chemical tank and the small hose usually carried upon the driver's seat is but an incidental feature, the body of the wagon being reserved for larger fire-engine hose. But in a properly designed automobile such apparatus can be sped to the scene of a fire with four to eight men at from 40 to 60 miles an hour Thus for a fire in a small suburban dwelling, in the majority of cases, a chemical engine brought close to the house with its 200 feet of ¾-inch hose, is able to extinguish an incipient fire. Such motor cars are built with engines from 24 to 50 horse-power Because of the peculiar service conditions they are usually of the air-cooled type to obviate danger of freezing in winter The tanks vary in capacity It is considered good practice to install two tanks, so that one can be refilled while the other is in use It would seem desirable that such chemical engines be supplied in the majority of fire departments to answer at once on the first alarm

The next step in the progress of the small motor chemical engine was to make it larger and to add to its equipment. Accordingly combination engines were designed which not only carried the chemical equipment but also hose for the following steam engine, scaling ladders, tools and other apparatus, thus enabling the men to prepare the way for more serious operations and saving valuable time In this field a number of very efficient types have been evolved

Next in mechanical development comes the motor

### A HEAVY TRUCK WITH FOUR WHEEL DRIVE

BY DR ALFRED GRADENWITZ

The adoption of trucks in rural districts is a difficult though very important problem of the automobile industry Bad roads and sandy soil create a number of difficulties which can be overcome only by special construction

One of the most important points seems to be the utilization of all four wheels for driving thus increasing the adhesion This is especially imperative in the case of heavy motor cars employed as tractors for load trains consisting of two or three vehicles where a weight of several tons acting on the fore axle can be utilized for adhesion

The Daimler Motor Works of Germany have constructed for a well known Berlin export firm a heavy truck with four wheel drive which is being shipped to South Africa in order there to take up its heavy duties in propelling as tractor a train of 10 to 15 tons This car shows a number of technical features of interest

The chassis is made of compressed sheet steel girders with compressed transverse beams and lateral shields The six cylinder explosion motor located in a three point suspension yields 60 horse power at the brake with 910 R P M This motor is of the familiar Daimler type with magneto-electric ignition

The maximum speed of the car is 10 miles per hour The low minimum speed ¼ mile an hour is remarkable thus fully utilizing the advantage of four wheel drive for the overcoming of gradients and traveling over sandy soil without increasing the dimensions of the gear case As only the fore wheels are steerable the rear wheels are driven through a toothed wheel drive

The cast steel wheels have broad rim flanges which are intended to prevent the vehicle from penetrating too deeply into the sand The solid rubber tires are pressed immediately on the wheels The fore wheels are steered essentially in the same manner as other cars through worm gearing The vehicle is equipped with four brakes operated independently of one another viz a gearing brake two differential brakes and one rear wheel brake The motor car which is designed for a useful load of [illegible] tons is able to haul two trailers of the same capacity while negotiating gradients of about 15 per cent with this total load of 130 hundredweight at a speed of 1¼ miles an hour

With a single trailer gradients of 7 to 8 per cent can be negotiated at a speed of 5⅝ miles so that the car seems well suited for making its way with the trailers also through deep sand

The weight of the car inclusive of its equipment is about 12 540 pounds of which about one-half falls on the fore axle so that about 6 270 pounds on the fore axle is utilized for adhesion

TRACTOR TRUCK (60-HORSE POWER 6-CYLINDER) HAULING A TRAILER

THE 60-HORSE-POWER MOTOR OF THE FOUR-WHEEL DRIVE TRUCK.

### THE PARSONS SPRING MOTOR WHEEL

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

The many well known defects of the pneumatic automobile tire have prompted many inventors to attempt to evolve an efficient and reliable substitute therefor without any sacrifice of resiliency The general trend of inventive effort has been to secure this quality by some elaborate arrangement of springs without however completely solving the problem

Early in 190[illegible] however the Hon R Clere Parsons M A M Inst C E directed his attention to this subject The object of his quest was to devise a wheel which should be as resilient as the pneumatic Although the first cost of such a wheel might be somewhat higher than the pneumatic such a difference would be more than compensated for by the lower maintenance expenses and the longer life of the wheel He has evolved the spring wheel illustrated in the accompanying photographs

Longitudinal section through Parsons spring wheel

The Panflex spring wheel comprises two essential parts—a double and independent channel rim consisting of (1) an outer steel channel aa into which a solid rubber tire is pressed and an inner channel bb formed by riveting thin rings of non oxidizable metal on either side of the outer channel and (2) inner radially disposed coil springs In a driving wheel the channel rim is furnished with corrugated segments having polished surfaces riveted around the internal surface of the steel channel for the dual purpose of transmitting the driving force of the engine and the retarding force of the brake from the wheel center to the outer rim In a non-driving wheel the corrugated segments are dispensed with, and are replaced by a smooth strip of hard bronze This channel has no connection with the spring wheel proper.

The general design of this inner section may be comprehensively gathered from a reference to the illustration showing the wheel center complete. It comprises an ordinary wooden-spoked wheel of small diameter having a groove around its circumference on each side of which is shrunk a steel band or tire in such a manner that a grooved space is left to receive the heads of the T bolts by which the spiral springs are secured to the rim of the wheel center. These spiral springs are of the ordinary cylindrical type so coiled as to fit into aluminium castings at either end and with such spaces between the coils that when compressed the steel is not overstrained. For protection against rust the springs are sherardized and moreover each end is thoroughly tinned for a length of about half a coil

The aluminium castings by which the springs are attached to the wheel center are of special design On one face they have a spiral tunnel or thread, so that the spring may easily screw into them, and are also provided with suitable lugs in order that they may be gripped by the T bolts A steel tube is also cast into the aluminium base which projects up the axis of the spring as shown in the illustration

The aluminium castings forming the caps for attachment to the outer ends of the springs are also provided with spiral tunnels on one face into which the spring screws while the other face has dovetailed grooves into which rubber strips of a section similar to those used for carriage tires are forced A hole is drilled into the center of these caps having a diameter considerably greater than that of the steel tube attached to the base so that a space is left between the tube and the casting The advantage of this arrangement is that in the event of the application of an excessive side force such as sudden and violent throwing in of the clutch or braking or the wheels being caught in a rut the tube comes into contact with the side of the hole thereby preventing the spring from being overstrained in any direction at right angles to its axis In the case of high powered automobiles, the rubber strips are replaced by a solid rubber pad vulcanised to a steel plate which is attached to the aluminium cap

The springs are inserted into the spiral tunnels at

their respective ends, and after correct adjustment are heated to a certain temperature, insufficient to injure their temper, and melted solder is then run in which unites with the tinning on the spring and securely combines the base and spring together in such a manner as to preclude any possibility of their becoming loosened.

The lower springs, i. e., those just above the point of the wheel's tread, are compressed under the weight of the vehicle while those at the top do not touch the circumference. The spring portion is therefore practically floating, for at no part is there any rigid connection between the inner and outer parts of the wheel. When the wheel is in motion the spring and caps in its lower portion take the whole of the weight of the vehicle and are brought tightly into contact with the rim, but do not shift their position relatively thereto. As the wheel moves forward the springs become disengaged and move round like the spokes of a rigid wheel, their places immediately being taken by others. The disengaged springs travel forward relatively to the rim in the direction in which the vehicle is moving. The result is that the central portion of the wheel makes a slightly greater number of revolutions than the outer rim in a given distance. At the same time, however, it is impossible for the inner part to travel round independently of the outer rim or tread of the wheel, since it is always tightly in contact therewith at the point of the wheel's contact with the ground, which is the point of application of the vehicle's weight; the rubber strips of the outer extremities of the springs establishing such adhesion upon the surface of the interior of the rim as to prevent any possibility of slipping. Yet there is no perceptible wear and tear upon the two contact surfaces. In the case of the driving wheel the gripping power of the spring members is very considerably augmented by having the corrugated surface as already described.

The successive compression of the springs as the wheel revolves is quite continuous and is effected with the utmost smoothness, as the spiral springs with their caps can be deflected in every direction. Sudden jerks or concussions cannot occur, which even with pneumatic tires are unpleasant features when traveling at high speed over a bad road surface.

It may be thought that the absence of rigid connection between the inner and outer parts of the wheel may be disadvantageous, but experience has quite conclusively demonstrated that no such drawback exists. It is practically impossible for any slipping between the two parts to occur even when the vehicle is badly driven. There is no friction between the rubbers in the free ends of the springs and the internal surface of the channel rim. The springs as it were walk round the inner circumference of the outer rim on a polished metallic surface, and are successively loaded with their due proportion of the car weight during each revolution. The moment the weight is applied to any spring the latter cannot possibly move relatively to the rim until the weight is released. Consequently there is an entire absence of friction, and the rubber shoes in the spring caps will last as long as the wheel tire. Even in the rare event of the rubbers of the spring end becoming damaged it is an insignificant item in renewal, but no such occurrence has yet been experienced, though wheels have been driven for thousands of miles. Even the entrance of dust or mud has no deteriorating effect upon the two surfaces.

The wheel has been severely tested upon a 28-36 horse-power Daimler motor in comparison with the heaviest make of English pneumatic tire. True, the "Panflex" wheel is somewhat heavier than the pneumatic, but it has been found that such is no disadvantage, the mileage possible per gallon of fuel under the selfsame conditions being approximately the same. Trials have shown that the average life of the outer solid rubber tire is from 10,000 to 12,000 miles, which is about two and a half times that of the ordinary pneumatic type. Though in first cost the "Panflex" wheel is more expensive than the pneumatic, this difference in initial outlay is soon recouped from the

A FAN DYNAMOMETER FOR TESTING MOTORS.

reduced running expenses. It has been found that the cost per mile with the pneumatic averages about 1.98 cents as compared with 0.48 cent for the spring wheel—a difference in the latter's favor of 1.50 cents. Moreover, as the wheel itself is practically everlasting, the renewal charges are limited to the solid rubber tire, which costs much less than a pneumatic of the same dimensions, and the rubber caps of the spring members. Occasionally, as the result of a very severe concussion or jolt, a spring might break. This can be easily and quickly replaced on the road, but as the deflection of the spring is limited in every direction by the central tube, the stress to which the steel is subjected need be no greater than that in the side springs supporting the automobile. Such an eventuality is therefore remote. Again, with this wheel in

LAMBERT AUTOMOBILE RAILWAY CAR BUILT FOR HARRIMAN BRANCH ROADS.

view of the ingenuity of its construction, the ever existing danger of side slipping is reduced to a negligible quantity owing to the flexibility of the wheel.

[illegible]

### AN AUTOMOBILE CAR FOR RAILWAYS.

The accompanying illustration shows a special car ordered by E. H. Harriman before his death, which is to be used on a private road running from a point on the Erie Railroad to the Harriman private residence.

The car is a Lambert friction drive and was ordered for the purpose of ascertaining whether a gasoline car for from 12 to 15 passengers could be utilized more economically than steam cars on branch roads on the Harriman lines. Whether a car of this character will come into general use will depend upon the result of experiments to be made.

### AN AUTOMOBILE BUFFET TENDER.

A novel automobile tender has been devised by Mr. G. L. Reeves. Mounted in the body across the rear end is a three-burner gasoline stove connected with a one-gallon gasoline tank. Next forward is a receptacle in which is fitted a complete cooking outfit, each article nesting and telescoping into the other. The outfit consists of two frying pans, four boiling vessels, coffee pot, twenty serving plates, three sauce pans and eight soup tins. To the left of the cooking outfit is a three-bin vegetable celler with tray lid for large cooking spoons, cake turners, carving forks, etc. To the right is a galvanized iron lined refrigerator containing six one-pint glass sealers, ice receptacle and large meat tray.

Immediately forward of the refrigerator and extending to the end of the bed is a seven-gallon water cooler. To the left of the water cooler is a thirteen-drawer cabinet intended for all grocery and cooking staples, knives, forks, spoons, tea towels, table covers, etc. In the little open court there is just room for two telescoping dish pans to disappear.

The accompanying picture showing the kitchen open indicates that the two covering lids when opened out form two spacious serving tables. These lids are covered on the inside with padded oilcloth, and on the outside with rainproof ducking. The meeting edge of one cover is provided with a patent leather flap and is held in place in transit by two large straps which buckle securely and make the tender rain and dust proof. A small brass hasp and lock is also furnished. A neat little folding dining table is strapped to the inside of one of these lids.

An extra broiler, a cooker for emergency, a pocket ax and a camp lantern strapped to an outside bracket complete the outfit.

The refrigerator and water cooler are fitted with drain cocks. A rigid pair of folding legs is provided to support the end of the body when disconnected from the auto.

The wheels have rubber tires and the several parts are so accurately nested that the tender moves even at twenty to twenty-five miles speed without noise and takes corners perfectly.

The tender weighs 475 pounds and the extra draft on the automobile is scarcely perceptible. It has been used in serving a great many roadside dinners and its entire practicability for such service established beyond doubt.

### A FAN DYNAMOMETER.

The standard type of fan dynamometer shown in the accompanying photograph has been devised by Joseph Tracy. It consists essentially of a metal standard carrying a horizontal steel shaft in large ball bearings. One end of this shaft is connected with the motor under test by a universally jointed extension shaft; the other end carries an overhung two-bladed fan, as shown. On the dynamometer shaft a small pulley fitted to a boss on the rear of the universal joint is belted to a larger pulley on the special tachometer which is mounted on top of the housing that carries the dynamometer shaft.

The tachometer of the standard fan dynamometer is provided with a double scale and single pointer, the inner scale showing the revolutions per minute and the outer scale the horse-power developed. The revolutions per minute scale is graduated progressively by divisions of 20 revolutions from 200 to 2,000 revolutions. The horse-power scale gives a minimum reading of 1 horse-power at 480 revolutions and a maximum reading of 70 horse-power at 1,980 revolutions. Consequently at all ordinary rates of motor speed a simultaneous reading of revolutions per minute can be obtained without any computation.

The standard fan dynamometer can be employed in testing motors on the block by making suitable connection between the jointed dynamometer shaft and the motor shaft, clutch or flywheel. It can also be used to test an automobile motor in position on the chassis by disconnecting the propeller shaft and substituting for it the jointed shaft of the dynamometer.

The standard dynamometer is designed to test motors of medium-sized cars. However, by the use of fan blades of greater or less area and suitable tachometer scales, the range of absorption and measurement of power can be varied between wide limits.

The Tenth National Automobile Show in Madison Square Garden afforded a good opportunity of inspecting the product of representative American makers. The exhibition brought out some novelties in construction and design which showed a gratifying tendency toward standardization. That the modern everyday motor car, generally known as a stock car, has left the misty zone of experiment and is now a practical and useful machine was strongly emphasized by the many performances in hill climbing, touring and racing contests of 1909. There is a comprehensive display at the Garden of duplicate models of the stock cars that competed successfully in the various sporting events of the year. Some of the original cars are shown. Thanks to the adoption of certain standards a new model need no longer be put through years of testing before it is entered in competition with other cars. Recently victories have been won by certain makes of cars that had scarcely competed in previous events.

THE BUFFET TENDER IN USE.

## ANTI JOY RIDE DEVICES

(*Continued from page 49.*)

made by flexible shaft connection with one of the vehicle wheels.

5. Combination mechanisms, embracing switch and engine hood lock and vibration recorder.

Some of these devices are now to all intents practically obsolete and out of the market, and there never has been any general demand for any of them except those intended merely to prevent meddlesome persons and mischievous children from tampering with machines left standing at the curb. The one class of device that is in almost universal use is the lock switch. Almost every large manufacturer of ignition spark coils and switches offers a current switch with a removable plug or lever or fitted with a lock and key by which the connection between the battery or magneto and the engine spark plugs can be broken and prevented from being re-established readily.

The type of switches with removable plug is illustrated in Fig. 1. Switches of this type are known as plug cut-out switches and are now designed to be used with a dual system of ignition, so that either the battery or magneto can be switched into use or the current from either of two batteries turned on. When the car is stopped, the metal plug, with insulated handle, which makes connection between the two terminals within the switch, as shown in the underside view, Fig. 1, is withdrawn and the circuit is broken. The engine cannot then be restarted until the plug has been replaced or electrical connection has been re-established in some other way. The plug is small and can be carried conveniently in the pocket.

A modification of this type which precludes the possibility of inserting a nail or piece of wire as a substitute for the plug is shown in Fig. 2, in which the switch lever is removable. There are numerous makes of such switches. The end of the lever engages by a slot or keyway with a post that prevents it from dropping off and at the same time assists in forming an electrical connection. The other end of the lever, fitted with a non-conducting composition handle, can be swung in an arc or complete circle to make contact with any desired contact button for use of batteries or magneto or to neutral "off" position.

A further development of the lock switch idea is seen in the auto lock plug (Fig. 3) in which a Yale lock is applied to a plug cut-out switch in such a way as positively to prevent the closing of the circuit through the switch without the proper key or its duplicate. The lock is placed directly above the plug socket, thus preventing the insertion of a nail or wire. The cut-out plug is connected with the mechanism of the lock so that it is thrust in or out by the turning of the key. The key cannot be removed from the lock until the circuit is broken. Each lock requires a different key, of which two duplicates are furnished to the purchaser.

The Yale lock, with sliding plug connection to take the place of the regular cut-out plug, can be fitted to various styles and makes of switches, being held on by screws of a special kind that cannot be removed except with a double-pointed wrench made just to fit the recess in the screw heads.

A device of somewhat similar characteristics to the foregoing is the break-circuit autolock (Fig. 4), which is manufactured in different forms for use on electric and gasoline vehicles. The type illustrated is for electric machines, but the operation of the two styles is similar. When the switch bar, just above the barrel of the Yale lock, is pulled forward it breaks the circuit and remains locked in this position until one of the two keys furnished with the device is inserted and given a half turn, when the connection is re-established automatically by the switch bar springing back into place. The electric vehicle lock is installed beneath the upholstering on the arm of the seat, where only the face of the lock is exposed. It takes the place of the ordinary cut-out plug, so that the operation of the lock is no additional bother.

The break-circuit lock for gasoline vehicles (Fig. 5) is made in different styles to apply to various systems of ignition. It is placed on the face of the coil box, taking the place of the usual switch. The switch-bar is round and provided with a winged head, so that it can be rotated to make connection with battery or magneto or to "off" position at will. When it is pulled forward it breaks the circuit completely. It is not necessary, however, to turn the bar or plug to neutral before locking or unlocking the switch.

Another means of accomplishing the purpose of preventing meddlesome persons from using a car left standing in the street or garage is the Rochester steering wheel lock (Fig. 6). This is hinged so that the hasp can be placed around the steering column. A steel pin at the back of the hasp enters a quarter-inch hole drilled through the outer and inner steering columns. When the hole in the inner column, to the top of which is keyed the steering hand wheel, has been brought opposite that in the outer post and the pin of the lock has been inserted through both, the front wheels cannot be turned.

The special feature of this device is the combination lock that renders unnecessary the use of a key, which may be mislaid, forgotten or lost. The barrel of the lock contains three tumblers each provided with a small lug on either side which engages with the corresponding lug on the next tumbler. Two tumblers are fastened to an internal top cap but are free to rotate on its center pin, while the third tumbler is removable and lies in the body or casing of the lock over a solid post that passes through its center. All the tumblers have a large notch in the periphery. To open the lock it is necessary to turn the external dial hand until all of the notches in the tumblers are brought into line, allowing the catch of the hasp to pass. This can be done only by working the lock combination.

The lock can be operated in the dark, as the dial is notched so that by starting at 0—which is distinguished by a large or open notch—the movement of the hand over the dial can be counted as the spring points drop successively into the serrations. When the lock is open, the combination can be changed in two minutes if desired. Except for the steel pin, this lock is made entirely of bronze and is made in different sizes to fit steering columns of different diameters. The manufacturers have also produced an adjustable hasp steering column lock made with four-tumbler combination and operated by a key.

In division *B* of group 2 is a new invention brought out this season under the name Bongartz autolock (Fig. 8). The device is designed as a lock to prevent use of the gear shift lever and, if desired, also of the brake lever. It consists of a simple lock incased in a polished heavy brass case to be attached to the side of the car or the footboard directly behind the lever quadrant, and a rod with a head on one end and a recess in the other end to be engaged by the plunger of the lock. With the gear-shift lever in neutral or in operative position, a hole of suitable size is drilled through the quadrant and shank of the lever to receive the rod. The lock case is then secured to the body or frame in such position that the hole for the end of the rod will be in alignment with the hole drilled through the quadrant. Now, when the car is stopped and the gears unmeshed, the rod can be inserted and engaged in the lock, when it will be impossible for anyone not possessing the key to start the machine.

A notable advantage possessed by this device is that, while preventing the car from being driven on the road, it does not interfere in any way with its movement by hand in the garage or with the adjusting and "tuning up" of the engine and its attachments by the chauffeur or workmen.

Not only is it essential that the unauthorized use of motor cars should be prevented, but it is almost equally desirable that some measure be taken to curb the speed enthusiasm of the hired chauffeur even when the owner is occupying the tonneau or interior of the limousine or landaulet. It is not altogether improbable that the owner needs a check on himself, as in the exhilaration of a good road, bracing atmosphere, and smoothly running car he may unwittingly let enthusiasm overstep discretion. Numerous efforts have been made to produce something that would accomplish such results by the sounding of audible signals when the car had attained to a certain speed or by the display of a prominent speed indicating device that could be read at a distance by every passer-by. The objections to these devices, however, were so obvious that they never met with favor except on the part of persons afflicted with motorphobia and lawmakers eager for popularity among their constituents.

A practical device intended to accomplish the same results in a much better and more effective way has been brought out recently for use in combination with a well known make of speedometer. This is the Jones automatic speed-control governor (Fig. 9). The mechanism consists essentially of a speed indicator, an automatic circuit breaker, a controller switch, and an electrically operated air valve, not indicated. The electric switch, which has five or more points of contact representing circuits, is operated by the action of the centrifugal governor of the speed indicator. The switch is so arranged that when the indicating hand of the speedometer shows a speed of ten miles an hour the switch will close the circuit through the first contact, when the velocity of the governor is such as to indicate fifteen miles an hour on the dial, the switch closes a circuit through the second contact, and so on up to any desired number of speeds or contacts.

By setting the pointer at any figure on the dial of the controller switch, the circuit can be made to close through the corresponding contact only and at the indicated speed. When this circuit is closed, it actuates the current to the primary of the induction or spark coil, thereby cutting off the spark from the engine. Or it may be arranged to operate the electrically controlled air valve or throttle, shutting off the supply of air or gas to the engine and thereby preventing the speed of the car from exceeding the indicated limit. As soon as the speed is reduced, the contact automatically cuts out and the engine gets its power again. Should the pointer of the controlling switch be set at an intermediate position, as in the illustration, the device will have no action whatever on the speed of the car.

As the controlling switch can be located almost anywhere in the car, it is evident that the owner or any occupant of the rear seat can limit the speed as desired, regardless of the driver. The device operates silently and is always on guard, giving a sense of security in passing through sections where the speed regulations are rigidly enforced.

An example of the vehicle movement indicating instruments classified under *A*, group 4, is the watch-dog vibration register (Fig. 10). This operates on the principle of the pedometer, a pendulum or weighted arm being held normally in a horizontal position by a light spring and caused to beat by reason of the momentum of the weight following every downward and upward movement of the instrument. Each beat of the pendulum releases a tooth in the train of gears which actuate the indicator hand and register figures on the dial. The dial is 2½ inches in diameter and is divided into 100 degrees. These divisions do not represent either hours or miles, but serve as a measure of the vibrations. Different cars oscillate vertically in different periods, it has been found, but each machine oscillates very nearly the same number of times for successive miles irrespective of its speed. Engine vibrations when the car is standing still do not affect the instrument, therefore the device makes no record except when the vehicle is in motion.

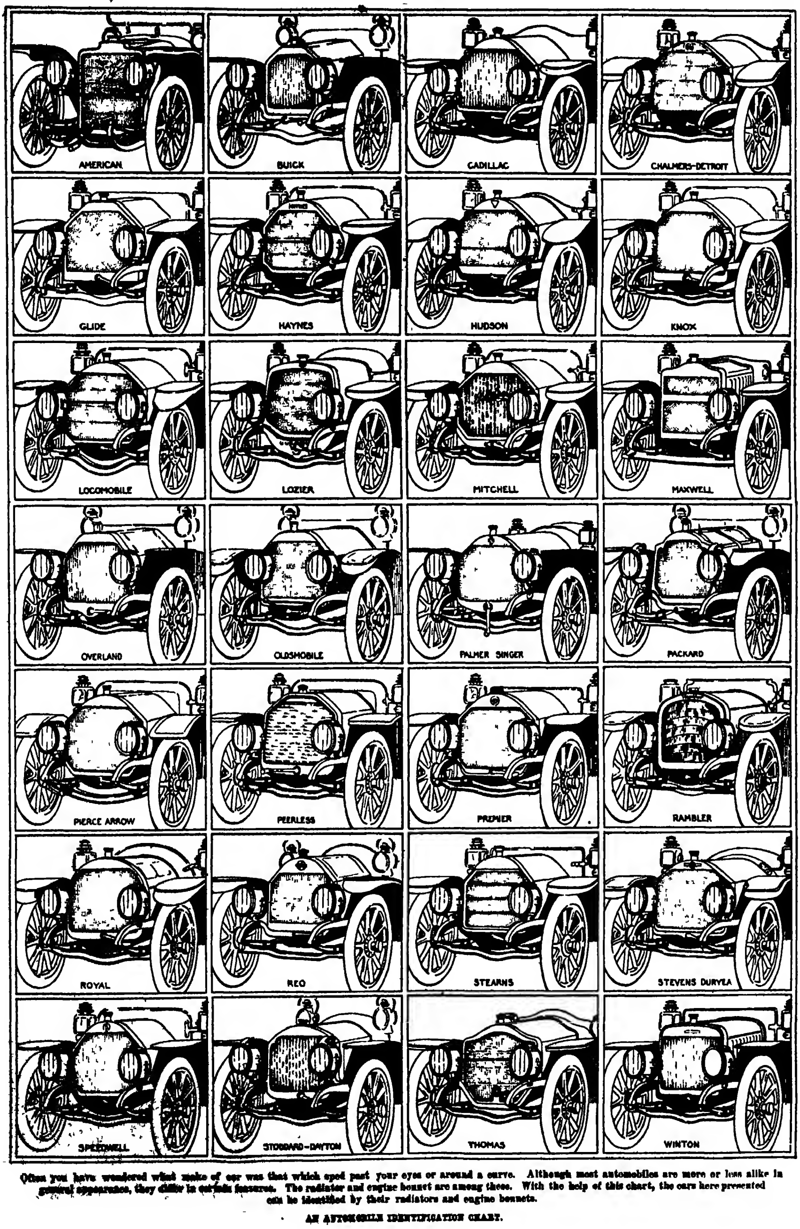
The instrument is intended to be attached permanently to the car so that it cannot be removed without the owner's knowledge and is securely sealed so that no one can tamper with the register. There is no shaft or wires connecting it with any working part of the automobile whose detachment or disconnection would render the recorder inoperative. The owner, having by observation determined that on his machine the instrument indicates say 10 points for each hour of travel, will have no difficulty in determining from the reading of the dial how many hours his machine has been driven after he last had it out.

A different type of vehicle movement indicator is represented by the Bullard recorder (Fig. 7). This provides a permanent record on paper of the hours during which the vehicle was used, the rate at which it was run during every mile traveled and the number and duration of stops made. It operates by a combination of clockwork movement and flexible shaft drive from one of the road wheels. The clock mechanism rotates a circular paper dial that makes one complete revolution every hour in the same direction as the hands of a clock. The dial is divided into sixty radial spaces representing minutes, every fifth line being heavier than the intermediate lines for convenience in reading. From center to circumference there are twelve circular divisions, also corresponding to the hours. Within the instrument is a stylus operated by both the clock and movement of the car, which makes a perforation in the paper dial for each quarter mile traveled, every fourth perforation being deeper than the others to indicate the completed mile. The stylus is at the extreme outside space when the instrument is set for a record and moves toward the center at the rate of one space each hour, being moved by the clock and requiring twelve hours to move across the dial, where it becomes inoperative until reset.

So long as the car stands idle the dial rotates without being punctured by the stylus, but for every quarter mile the car travels (if a pleasure vehicle) one perforation is made. And according as the machine is driven fast or slow the holes are close together or farther part. At the rate of a mile in four minutes, or fifteen miles an hour, there will be just one hole for each radial division, while at sixty miles an hour there would be four. By examination of the dial it is possible to determine the exact hour and minute at which the car was started and stopped. Combined with the instrument is a tiny odometer which registers the total mileage up to 10,000. The instrument depends for operation on a simple train of gears and ordinary clockwork and the same connection with the road wheels as every speed indicator. The inventor decided upon the perforating system because it cannot be tampered with without detection, no jar or jolt of the car can derange it and cold weather or dry cannot render it inoperative. For use on commercial vehicles, which move at a slower rate of speed, the stylus is made to perforate for every eighth mile instead of every quarter.

Much the most comprehensive invention to prevent the unauthorized use of motor cars that has been made is that of Leon Ottinger of New York city (Fig. 11). It is called the [illegible] recording lock, this trade name being adopted because of the combination of functions it performs, which also brings it into group 5 of our classification. By a single operation it locks both the ignition switch and the hood over the engine compartment, so that it is impossible to raise the hood without the use of the Yale key that fits the lock. Provision can also be made, if desired, for locking

(Continued on page [illegible].)



Often you have wondered what make of car was that which sped past your eyes or around a curve. Although most automobiles are more or less alike in general appearance, they differ in certain features. The radiator and engine bonnet are among these. With the help of this chart, the cars here presented can be identified by their radiators and engine bonnets.

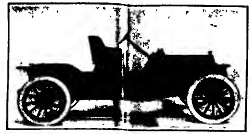
AN AUTOMOBILE IDENTIFICATION CHART.

**Chalmers-Detroit 40 horse power pony tonneau.**

Cone clutch; four cylinders cast in pairs; bore 5 inches by [illegible] inches stroke; water cooling, with honeycomb radiator; jump spark ignition; shaft drive; selective sliding gear transmission. Price $1,750.

**Cartercar, 35 horse-power.**

Motor, bore [illegible] inches by [illegible] inches stroke; four cylinders cast in pairs; low tension ignition; friction transmission; non-floating rear axle; chain in-oil drive; one-lever control. Price $1,400.

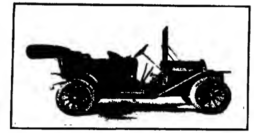


**Schacht convertible car.**

Motor, opposed water cooled, 5¼ inches bore by 4½ inches stroke; planetary transmission; chain drive; jump spark ignition; internal expanding brakes on rear wheels. Price, $675.

**Brush runabout.**

10 horse-power motor; balanced single cylinder; 4 cycle, vertical, 4 inches bore by 5 inches stroke; three point suspension; internal gear transmission; bevel gear drive; single hand lever control; internal expanding brakes on rear sprocket hubs. Price $485.



**Overland touring car, 35-40 horse power.**

Cone clutch; contracting and expanding brakes; four cylinders cast separately; bore 4¼ inches by 4½ inches stroke; water cooled with flat vertical tube radiator; shaft drive; selective sliding gear transmission. Price $1,[illegible].

**Franklin 42-horse power touring car.**

Multiple disk clutch; 6 cylinders cast separately; bore 4[illegible] inches by 4 inches stroke; air cooled; jump spark ignition; shaft drive; selective sliding gear transmission. Price $[illegible].

**Hupmobile runabout.**

Horse power 2[illegible]; cylinders 4 arranged in pairs; bore, 3¼ inches; stroke, 3⅜ inches; water cooled; ignition high tension Bosch magneto; shaft drive; universal joint; selective gear transmission; two foot and two emergency brakes. Price $750.

**Premier 40-horse-power touring car.**

Four cylinders cast in pairs; bore, 4½ inches by 5¼ inches stroke; water cooled with cellular radiator; make-and-break ignition; shaft drive; selective sliding gear transmission. Price, $2,[illegible].

**Rambler touring car.**

Motor; bore 5 inches; stroke 5[illegible] inches; 4 cylinders; ignition high tension; transmission [illegible] selective; horse power, 45; brakes on hubs. Price $2,[illegible].

**Oldsmobile 40-horse-power special touring car.**

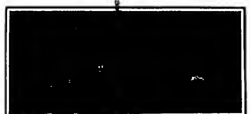
Four cylinders; bore 4¾ inches; stroke [illegible] inches; water cooled; jump spark ignition; high tension magneto and dry battery; shaft drive; selective sliding gear transmission. Price $3,000.

**Winton touring car.**

Horse power (A. L. A. M. rating) [illegible]; [illegible] cylinders; bore [illegible] inches; stroke [illegible] inches; water cooled; jump spark ignition; high tension magneto and storage battery; shaft drive; selective sliding gear transmission. Price $3,000.

**Pierce Arrow touring car.**

Horse power (A. L. A. M. rating) 48; 6 cylinders; bore 4½ inches; stroke 4¾ inches; water cooled; ignition jump spark; shaft drive; selective sliding gear transmission. Price, $5,000.



**Cadillac 30-[illegible] power limousine.**

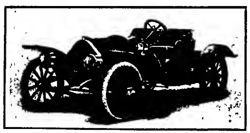
Cone clutch; contracting and expanding [illegible] on rear wheels; 4 cylinders cast separately; bore 4¼ inches by stroke 4½ inches; [illegible] cooled with tubular radiator; jump spark ignition; shaft drive; selective [illegible] gear transmission. Price, $3,000.

**Pope Hartford 40-horse power touring car.**

Four cylinders; bore 4[illegible] inches; stroke 5[illegible] inches; water cooled; jump spark ignition; expanding brake on propeller shaft and both rear wheels; shaft drive; selective sliding gear transmission. Price $2,750.

**Baker electric runabout.**

Bevel gear shaft drive; semi-floating rear axle with ball bearings; motor four pole series wound; controller continuous torque drum type with [illegible] speeds forward and [illegible] reverse; 2 brakes, 1 internal and 1 emergency. Price $2,000.



**The K-R-I-T runabout.**

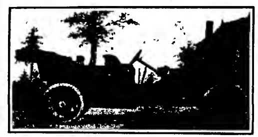
Wheel base, 96 inches; [illegible]; sliding gear transmission; horse power 22½; multiple disk clutch; weight 1,300 pounds. Price $[illegible].

**Maxwell 40-horse-power touring car.**

Four cylinders; bore 4[illegible] inches; stroke 4¾ inches; water cooled; jump spark ignition; low tension magneto and dry battery; shaft drive; progressive sliding gear transmission. Price, $1,[illegible].

**Royal Tourist touring car.**

Horse-power (A. L. A. M. rating), 40; cylinders, 4; bore, 5¼ inches; stroke, 5 inches; water cooled; jump spark ignition; shaft drive; transmission, selective sliding gear; expanding brakes. Price, $4,500.



**Mitchell touring car.**

Horse-power (A. L. A. M. rating) 43.8; 6 cylinders; bore 4¼ inches; stroke, 5 inches; water cooled; jump spark ignition; high tension magneto and dry battery; shaft drive; transmission selective sliding gear. Price, $2,000.

**Stevens Duryea touring car.**

Horse power (A. L. A. M. rating) [illegible]; [illegible] cylinders; bore [illegible] inches; stroke [illegible] inches; water cooled; jump spark ignition; high tension magneto and dry battery; shaft drive; transmission progressive sliding gear. Price $[illegible].

**Packard 30-horse power touring car.**

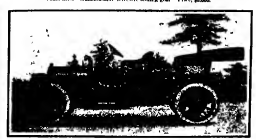
Four cylinders; bore 5 inches; stroke 5½ inches; water cooled; jump spark ignition; low tension magneto and storage battery; shaft drive; progressive sliding gear transmission. Price, $4,200.

**Peerless 30-horse-power touring car.**

Four cylinders cast in pairs; bore, 4⅝ inches; stroke, 5½ inches; water cooled, with tubular radiator; jump spark ignition, with high tension ignition and storage battery; selective sliding gear transmission. Price, $4,475.

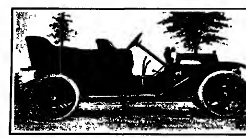
**The [illegible] runabout.**

Cone clutch; horse-power 22.5; four [illegible] cast en bloc; bore, 3¾ inches by 4½ inches stroke; water cooled; jump spark [illegible]; selective sliding gear transmission; contracting brake on propeller shaft [illegible] on both rear wheels. Price, $900.



**White 20-horse-power gasoline car.**

Cone clutch; 4 cylinders cast en bloc; bore, 3¾ inches; stroke, 5½ inches; water cooled; jump spark ignition with high tension magneto; shaft drive; selective sliding gear transmission. Price, $2,000.

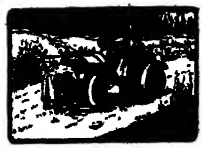


**Everitt-Metzger-Flanders 30-horse-power touring car.**

Wheel base, 108 inches; four cylinders cast in pairs; bore 4 inches; stroke 4½ inches; water cooled; jump spark ignition; selective sliding gear transmission. Price, $1,350.

THE CARS OF 19[illegible]—BIG AND LITTLE.

# MAKING YOUR OWN REPAIRS.



BY ROGER B. WHITMAN.

To one who is familiar with the methods employed in the average automobile repair shop it is not surprising that owners of cars complain of the size of their bills. The principal charge is usually for labor at so much an hour but there is no way in which the owner can assure himself that part of the time charged for was not wasted. The difficulty of checking a labor charge is an inducement to a mild form of swindling and it must be admitted that there are shops in which an hour's work by an untrained boy is charged for at the rate for skilled labor. Then again time may be wasted unintentionally. It is not unusual to find that after assembling an engine or a gearset the work must be undone in order to fit an overlooked part or to correct an adjustment that should have been attended to in the first place and in such an event the total time occupied is usually charged to the owner of the car.

When the prospective purchaser of an automobile is of a properly inquiring turn of mind he will ask his friends to let him see their bills for repairs and maintenance and will probably gain the impression that automobiling is an expensive diversion. If he has any mechanical ability however he will realize that three-quarters of the work charged for could have been done with simple tools and an ordinary knowledge of their use.

Aside from the economy of it the owner who does his own work becomes so familiar with the mechanism that it is instinctive with him to recognize the signs of coming trouble. He corrects faults at their inception and by so doing he obviates an otherwise inevitable delay and expense.

The following notes are offered as suggestions to the owner who desires to render himself independent of the repair shop.

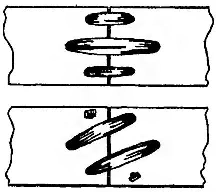
VALVE GRINDING.

At more or less frequent intervals the valves of a gasoline engine and particularly the exhaust valves will become roughened and pitted. When they are in this condition they cannot be expected to retain the compressed gases and in consequence the engine can not deliver its full power. It then becomes necessary to grind in the valves which is accomplished by introducing an abrasive between the valve and its seat and rotating the valve under light pressure until the surfaces are worn smooth. This is usually considered to be a job for a repair man but as it is patience rather than skill that is required the car owner need not hesitate to undertake it.

Before grinding can begin the valve must be relieved from the pressure of its spring. In many engines the valve seat and spring are contained in a cage that is easily removed and the detaching of the spring from the stem is an easy matter. When the valve seat is integral with the cylinder the spring may be compressed by means of a special tool or by a flat metal bar used as a lever. To prevent the valve from moving a small block of wood may be placed between the valve disk and the valve cap. When the spring is compressed the device through which it acts on the valve stem may be removed. The valve may then be taken out through the valve cap opening.

When a valve is in bad condition the surfaces of the disk and seat are rough and pitted. It is not necessary to continue the grinding process until the entire width of the surfaces is smooth for a narrower ring or belt is sufficient to retain the gases if it is continuous and uninterrupted. Finely powdered emery mixed with machine oil is a satisfactory abrasive but whatever is used great care must be taken to keep it out of the cylinder and away from the bearing surfaces. The passage between the valve pocket and cylinder should be tightly plugged with cotton waste, a string tied to it facilitating its removal when the work is completed.

For a badly worn valve the first grinding is done with coarse emery which is later replaced by a finer grade to give the requisite smoothness. To apply the abrasive dip the finger tip in machine oil and then in dry emery the small quantity that adheres being applied to the valve surface. The valve is then replaced on its seat and rotated by means of a screw driver. A bit brace or breast drill may be used but excellent results may be obtained by means of an 8 inch or 12 inch screwdriver with a round grooved handle which is held between the extended palms. A continuous rotary motion in one direction will tend to wear the valve oval and it is necessary to turn it first in one direction and then equally in the other. A slight back and forth motion of the hands will give this result and as only a light pressure is necessary it should not prove tiresome.



LACING A FAN BELT

In order to preserve the true circular form of the valve and seat the valve should be lifted after twenty or thirty turns and replaced on its seat in a new position. To facilitate this a few turns of a helical spring may be placed in the valve pocket under the disk its size and strength being such that the valve will be slightly lifted from its seat when pressure is taken off the screwdriver. The location of the spring is shown in the diagram.

When the valve surfaces appear smooth all traces of the emery should be washed away with gasoline care being taken that it does not lodge in the cylinder valve stem and push rod guides or other bearing parts. To test the fit make pencil marks on the valve seat and give the valve a turn or two with the screwdriver. If the fit is correct the marks will be erased.

The replacing of the valve spring is greatly simplified if it is compressed in a vise and bound in the compressed state by light iron or copper wires passed through it lengthways. The spring may then be placed on the valve stem and the holding device attached after which the wires are cut.

"TAKING DOWN" A MACHINE.

When the average man finds it necessary to take any kind of a machine to pieces he is inclined to consider results rather than methods. He unscrews all of the nuts and bolts that are to be seen, and as each comes off he lays it down wherever there is room to put it regardless of order or system. He is not likely to notice the exact position of a piece before he takes it off and in general is unobservant of the foresight that would go far to simplify the reassembling. If time is not an object he will eventually get all the parts properly rebuilt but if he aspires to be a good workman he must learn to be methodical in everything that he does.

The first step in dismounting any part of an automobile is to ascertain what holds it in position what other parts may have to be displaced in order to get at it and what parts may be released by its removal. To take off an inlet manifold for instance it may first be necessary to remove the carbureter which in turn will require the disconnection of the gasoline pipe and throttle control.

The plan of action having been determined work may begin. It will greatly facilitate reassembling if nuts bolts screws and other small parts are placed in boxes the parts belonging to the inlet pipe in one, inspection plate bolts in another and so on. If these parts are laid indiscriminately on the engine and frame they are only too likely to fall into hand holes and other openings and aside from the difficulty of recovering them they must then be sorted.

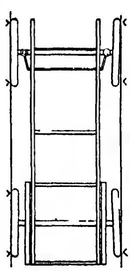
Where several parts are alike in shape and size—valve caps for instance—it should not be taken for granted that they are interchangeable. Each may have been fitted to its particular location and on the chance of this they should be marked before being removed so that there may be no error in returning them. Some manufacturers are careful to mark all parts by letter or figure or with a prick punch and when this is the case the marks should be followed absolutely. In the case of gears it is usual to make three punch marks at the point of meshing. To reassemble them correctly it is then necessary only to place the marked tooth of one gear between the two marked teeth of the other.

When taking off a cylinder the connecting rod should be blocked or supported. Otherwise the weight of the piston will bring it sharply against the crank case which may suffer in consequence. If the cylinders are to remain off for any length of time they should be plugged with cotton waste at all openings and several thicknesses of paper should be tied around the pistons.

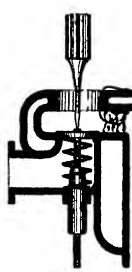
In reassembling, all nuts bolts and screws should be cleaned and oiled before being replaced. Every bolt has its wrench of appropriate size with which it is hardly possible to exert a breakage strain. When an 18 inch wrench is used on a ¼ inch bolt there is every possibility of the bolt head being twisted off before the operator realizes that it is in danger.

If the parts of a properly made machine do not come off with reasonable freeness when the bolts and nuts are removed force should be avoided until it is proven to be necessary. Taper pins keys and unsuspected set screws are frequently responsible and as they must be accurately replaced their location and direction should be noted and remembered.

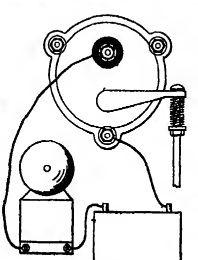
It is poor policy to rush a piece of work and after a few experiences with compression water and gasoline leaks that could be avoided by giving more time to the job in hand the motorist will hang in his shop the motto "Go slow, go sure," and abide by it.



LINING UP THE WHEELS.



GRINDING A VALVE.



TIMING AN IGNITER.

LUBRICATING THE SPRINGS.

It is the practice among automobile manufacturers to fit grease cups to the shackles and eyes of the springs, and the user of a car is inclined to take it for granted that there is nothing more to do for the springs than to turn down these cups occasionally. It should be noted however that the spring leaves require lubrication at least once a season. There is a continual sliding motion of the leaves when the spring is in action. If the surfaces are not lubricated they will be subject to undue wear and eventual breakage.

The proper lubricant is a mixture of graphite and

(Continued on page 74.)

## AUTOMOBILE NOTES.

Undoubtedly the weak points in the pneumatic tire whether it be that of a cycle or motor vehicle, are its cost of up-keep and liability to puncture It is clear that the direction in which improvements have been made is in the thickening of the tread, so as not only to render punctures less frequent, but also to give the tire a longer life, and thus save expense In some makes of tire, the increase in thickness of the tread of the outer cover, and in others that of the inner tube, has been so great that most of the resiliency has been lost, and the tire practically becomes a solid one In order to restore the resiliency, it has been proposed to reduce the air pressure in the internal tube, but this causes not only excessive internal friction between the inner tube and the cover, which is in any case difficult to avoid altogether, but also produces a large flat surface, in contact with the road, which adds considerably to the tractive resistance, especially when the surface of the road is soft The evils of traveling on slack pneumatic tires are known to all cycle riders, and are carefully avoided by keeping them inflated with a sufficient air pressure The air pressure which it is necessary to maintain in the inner tubes of the pneumatic tires of a heavy vehicle is not less than 100 pounds per square inch, and should the slightest defect occur which allows the air to escape, the tire is not only rendered useless to support the vehicle but is speedily damaged if the collapse is not quickly repaired.

At the Tenth National Automobile Show in Madison Square Garden there will be the only complete motor cycle exhibit in New York in 1910 by the Motorcycle Manufacturers' Association An inspection of the new models on display there proves that the motorcycle not only is a pleasure vehicle for poor and rich alike—ranging in price from $100 for the small single-cylinder machine to more than $500 for the expensive four cylinder touring model *de luxe*—but a utility vehicle as well General refinement seems to be the tendency for 1910 Many improvements have been made in spring forks as the result of hard road contests during the past year Some of the machines appear with spring frames and longer wheel base, all of which make for the comfort of the rider As regards the appearance of the motorcycle better quality and more lasting enamel as well as heavier plating seems to be the aim of the manufacturers. Handlebar control is practically universal, and magneto ignition will be more popular than ever, several of the makers having decided to make this type of ignition standard equipment, instead of optional as heretofore Increased power apparently is a general tendency, and mechanical oilers are also in evidence, which eliminate guesswork in lubrication, one of the bugbears of riding Several of the manufacturers have decided to abolish the muffler cut-out which, with the muffler improvement noticeable, should make the motorcycle of 1910 as silent a steed as its forerunner, the bicycle.

Two Chalmers-Detroit chassis models will be manufactured in 1910, the "Thirty" and the "Forty," both a continuation of those presented for 1909 The changes, while important, are not in any case radical The new Chalmers-Detroit "Thirty" will have a 115-inch wheel base, three inches longer than the 1909 Forty It will have 34-inch wheels—two inches larger than last season The hood will be three inches longer and two inches higher—in keeping with the larger body The tonneau will be large and roomy The "Thirty" motor is more powerful this year than last The 1910 "Forty" has a 122 inch wheel base—ten inches longer than last season It has 36-inch wheels, and room for seven passengers. The 1909 "Forty" was a five-passenger car

The Tenth National Automobile Show in Madison Square Garden eclipses any former exhibition of motor cars, motorcycles, and accessories ever held in the famous building There is a total of 323 different displays, of which there are 54 exhibits of complete cars besides 246 exhibits of accessories and parts, and 23 motorcycle exhibits Even with an increase over last year of more than 7 000 feet of exhibition space which the show managers by ingenious methods were able to eke out of the Garden interior, there is not one foot of unused space available for exhibition purposes. This situation is indeed a striking commentary on the growth of the industry when it is realized that at the first automobile show in this country, in 1900, there were only 60 exhibitors who displayed their product in the Garden

Noteworthy among the runabouts costing much less than $1,000 is the Hupmobile made by the Hupp Motor Car Company Detroit Mich In its construction the makers have endeavored to impart to their runabout all the staunchness excellent workmanship, and trustworthiness of the seven passenger touring car The four-cylinder engine is of 20 horse-power, with four cylinders having a stroke of 3⅜ inches and a bore of 3¼ inches. Water cooling is employed. The transmission is of the selective sliding gear type. The multiple disk clutch runs in oil. The rear axle is shaft driven. There are two foot brakes and two emergency brakes. A Bosch high-tension magneto is provided.

Something new in the Garden show is to be found in nearly every one of the models exhibited. Some of the new points of interest are found in axles, transmissions, and in lubricating systems. In bodies, a type that seems to be gaining favor is the four-passenger surrey, which is but a tonneau without doors, built low in the back and sides, yet providing plenty of seating space. The cars at the Garden show range from the costliest on the market down to the little runabout that is cheap enough for anyone.

In 1901, Mr Byron J Carter, then of Jackson, Mich, realizing the shortcomings of geared transmissions as used in automobiles, began experiments for improvements, being naturally attracted to the friction system because of its manifest advantages. After months of careful research, the first Cartercar friction-driven automobile appeared in the summer of 1902. This automobile was of the runabout type, and in addition to the radical improvement in transmission parts, was well designed and constructed. The car has run more than 25,000 miles, and is now, without repairs, apparently in condition for additional service

A remarkable car has been brought out by the Schacht Manufacturing Company, of Cleveland, Ohio The car in question is ingeniously convertible Ordinarily it is a runabout. By the addition of a surrey seat the runabout is transformed into a four-passenger family car The same runabout, by the employment of a special box back, is converted into a light delivery car The vehicle is illustrated on the double page of cars appearing in this issue.

The present four-cylinder Cartercar may be regarded as an improvement of the former two-cylinder model, without a single radical change. This car will appear in the coming season in two sizes. Both have the Carter friction transmission, the nucleus around which the first Cartercar was built

The most grueling sort of endurance contest in which motor cars have participated are 24 hour races As a rule out of about fifteen cars starting in these events only five of them finish at all, the remainder breaking down in the course of the contest from some mechanical weakness. Some cars have started in eight or more of these terrific grinds and have never finished once At the 24 hour race held at the A Y P Exposition at Seattle, a Hudson "Twenty" stock car swept around the course for hours at a time making mile after mile with the utmost consistency in a 1 15 clip The construction of this car is interesting, when its low selling price is considered The rear axle is of the semi floating type, shaft driven, and is strongly reinforced at the points where the greatest shocks and strains occur Two large double-acting brakes are provided at each end of the rear axle The car is built for the man who is satisfied with a speed of 55 miles an hour The motor, four-cylinder vertical, water cooled, is simple, very strong, and amply powerful The transmission is the three-speed sliding gear selective type used on all standard cars.

### Official Meteorological Summary, New York, N. Y., December, 1909.

Atmospheric pressure Highest, 30 49, lowest, 28 97, mean, 29 92 Temperature Highest, 54, date, 6th, lowest, 6, date, 30th, mean of warmest day, 45, date, 6th, coolest day, 11 5, date, 30th, mean of maximum for the month, 36 8, mean of minimum, 26 1, absolute mean, 31 4, normal, 34 1, deficiency compared with the mean of 39 years, 2 7 Warmest mean temperature of December, 42, in 1891, coolest mean, 25, in 1876. Absolute maximum and minimum of December for 39 years, 68 and —6. Average daily excess since January 1st, 0 7. Precipitation 5.00, greatest in 24 hours, 2 92, date, 13th, 14th, average for December for 39 years, 3 43 Accumulated deficiency since January 1st, 2 87 Greatest precipitation, 6 66, in 1884, least, 0 95, in 1877 Wind Prevailing direction, west, total movement, 11,964 miles, average hourly velocity, 16 1; maximum velocity, 58 miles per hour. Weather Clear days, 14, partly cloudy, 8, cloudy, 9; on which 0.01 or more of precipitation occurred, 6 Sleet, 13th Snow-fall 11 4

Many an inventor has probably wondered whether the patent law forbids his experimenting with a patented invention The answer is It all depends upon the character of the experiment. Suppose that an inventor is interested in flying machines, and that his primary object is to improve the Wright machine. Has he the privilege of building a Wright machine himself and flying it, in order to study its performance as well as to acquaint himself with the art of flying? We think not. He has no right to build the machine for the purpose of learning how to fly or for studying its performance in any way. Had he bought the machine from the Wright brothers or their licensees he would undoubtedly have the right to use the machine in that way

### 1910 Registrations and Licenses.

Inasmuch as considerable doubt, and in some cases confusion, seems to arise in regard to the 1910 registrations and licenses in different States, the Bureau of Tours of the Automobile Club of America has issued a chart showing just what States require registration or license for the new year, where renewals are necessary, and where the old registration or license is still operative. A synopsis of this chart for New York, New Jersey, Pennsylvania, Massachusetts, Connecticut, and Rhode Island is as follows:

New York.—Registration of cars in New York State are perpetual on the car originally registered. If car changes ownership, the new owner must re-register same. If new car is purchased, same must be registered. Transfers are not made.

New Jersey.—Registration of car and driving license is required annually, and same can be procured direct from the Bureau of Tours of the Club.

Pennsylvania.—Pennsylvania requires both registration of car and driving license annually, application blanks for which can be procured from the Bureau of Tours. Non-residents, of States that reciprocate, are allowed ten days' exemption from registration.

Massachusetts.—Registration required annually; also driving license for owner and chauffeur Owner's driving license perpetual; chauffeur's driving license good for one year from date of issue—the latter renewed for 50 cents Non-residents exempt for seven successive days Non resident owners may drive, but chauffeurs must procure driving license The Bureau of Tours can procure temporary driving license for non-resident chauffeurs, provided chauffeur can procure certificates of good character and recommendations.

Connecticut.—Registrations are annual, expiring December 31st Annual driving license required by owner or chauffeur Non-residents exempt for ten days from registration and driving licenses.

Rhode Island.—Registration and driving license required Fees of registration based upon horse-power Non-residents duly registered in home State are exempt for ten days.

### Electron—A Metal Lighter than Aluminium.

According to Kosmos, a technical review appearing at Pforzheim, the Griesheim-Electron works exhibited at the aeronautic exposition at Frankfort-on-the-Main its novel patented alloy, the metal "electron," which is claimed to be much lighter than aluminium and at the same time much more durable.

The lightest metal employed for technical purposes up to the present time has been aluminium and some alloys of aluminium, the strength and the durability of which are however lower than those of the new metal The density of aluminium and its alloys has been nearly 3, and they are about twice as heavy as electron The chemical works of Griesheim-Electron has discovered that magnesia is utilizable for technical purposes. By the admixture of magnesia, the price of which is comparatively low, with one or two metals, an alloy is produced of a density of 1 75 to 2, possessing great solidity, strength, and elasticity, and at the same time readily workable The color of these alloys resembles that of silver, and they possess great sonorous quality

The new metal is said to behave very well as regards change of temperature, and it responds to all technical requirements, in the air it becomes covered with a coating of protective oxide. As cast metal, it offers a resistance up to 18 kilogrammes per square millimeter and has at the same time an extension capacity up to 5 per cent. By the processes of condensation, such as compression, rolling, etc., the physical properties of this metal, e. g., strength and elasticity, can be materially improved without its density being increased to any considerable extent. We may thus obtain a tensile resistance up to 35 kilogrammes per square millimeter, and an extension capacity as high as 16 per cent.

By varying the quantity of metal in the alloy and the method of using it, the quantities of electron may be varied within very wide limits. The uses of the metal are therefore very numerous. It is particularly desirable where the object is to obtain extreme lightness and at the same time great strength The physical properties of the metal electron are claimed to be superior to those of aluminium, the proportionate quantity necessary for technical purposes is 60 per cent or more, compared with the weight of aluminium.

It is anticipated that electron will prove exceedingly useful in the construction of airships and automobiles inasmuch as in most of its properties it is superior to aluminium and its alloys. In manufacturing the same object, one would require at least 40 per cent less of electron than of aluminium.

The "Zeppelin" airship requires 6,000 kilogrammes of aluminium, which could be replaced by [illegible] kilogrammes of electron. A large automobile contains, in its mechanism, about 600 kilogrammes of aluminium, which could be replaced, according to the statements of the exhibitors, by [illegible] kilogrammes of electron.

### THE MOTOR CAR AND THE ROAD.

(Continued from page 47.)

permanent binders include the petroleums containing an asphaltic base, the residues of such petroleums, the heavy tars, pitches, and numerous oil, tar, and asphalt preparations. In addition to these, a few special materials have been the subject of experiment, such, for example, as the waste product from the beet and cane sugar factories. In some instances glue and bichromate of potash have been added to oil or tar emulsions to cause the residue upon the road surface to harden after the volatile products have evaporated. Waste sulphite liquors from wood pulp have been employed with some success in a concentrated form, and, in fact, the list might be indefinitely extended. The essential requisite in a dust preventive is its binding power, and it naturally follows that the experiments will cover a wide field.

Water, while usually the most abundant and cheapest material, is very often, because of the frequency with which it must be applied, the most expensive to use. Its binding power is almost entirely due to capillarity. The value of the salt solutions commonly used lies in the hygroscopic character of the dissolved salt, which, having considerable affinity for water, keeps the road surface in a moist condition long after a surface treated with water alone would have become dry through evaporation. The light oils and tars, as well as the oil and tar emulsions, are dependent for their effect upon the retention by the road surface of a comparatively small amount of true binding base after the volatile products have evaporated This base proves effective only as long as it retains its binding power When the binding power is destroyed, it is necessary to apply more material If the base is an exceptionally good one, the accumulated products finally harden the road surface and prevent wear to some extent.

The heavy oils and tars differ from the lighter products in that they contain a much greater amount of asphaltum, which constitutes the binding base The results are, therefore, of a more lasting character, and hence the name permanent binders. The semi-solid and solid preparations usually contain a still greater amount of binder With some few exceptions, all of the true binders are bitumens, and these bitumens may be either natural or artificial

The usual method of applying these materials to the road surface is by sprinkling. The temporary binders can usually be applied cold, but the permanent binders, because of their much greater viscosity, must be heated until sufficiently fluid In England and France the use of coal tar is practised to a large extent and their methods of application have been highly developed. Machines are in general use which are self-propelling and in which the tar is heated and then applied to the road surface as a spray under high pressure. These so-called "tar sprayers" are not only very economical in the use of tar, but insure a more even distribution and better penetration of the road surface than it is possible to obtain in almost any other way.

In the construction of dustless roads, the crucial question is that of cost. Automobiles have but little destructive effect on pavements, but these are in general too costly for country roads. The effort must be to develop a form of construction which will withstand fast automobile traffic and at the same time be within the financial resources of the community This is largely being done at present by the use of a bituminous binder instead of the rock dust. The two methods generally employed are known as the penetration and the mixing method. In the former, the hot liquid binder is sprinkled or sprayed over the stone and allowed to penetrate through the voids and coat the stones usually to a depth of two or three inches. Some of the devices in use force the binder into the road surface by means of heavy air pressure. In the mixing method, the stones and binder are thoroughly mixed, either by hand or machine, so that each stone is covered with a thin film of the binder This method in general insures the better and more even distribution of the binder throughout the road surface

The material used for the binder varies very largely with different sections In England and France the tars are used very largely In the western portion of the United States, the heavy asphaltic oils of California are used almost exclusively, while in other sections we find that tars, residuum oils, liquid asphalts, and various proprietary compounds are being used.

One of the chief causes of the great number of failures which have been recorded in the use of bituminous road materials is the failure of the user, as well as manufacturer, to understand certain fundemental principles. To many, a tar is simply a tar and oil an oil, while in reality there is a vast difference sometimes even in the tars produced at the same works. The oils also range from those of a paraffine base to those almost wholly asphaltic Thus a concise knowledge of the character of the product, the process followed in its preparation, and the effect which varying conditions will have upon it is necessary in order to avoid costly mistakes.

### THE MIDDLE WEST AND THE AUTOMOBILE INDUSTRY

(Continued from page 48.)

that the freight has usually been added to the purchase price of the car, and has gone against the consumer, there are many cases in the past, and there will be many more in future, where the cars are sold directly at the catalogue price For that reason, the location of factories in the middle West was ideal, for it is in truth the center of the automobile-buying public

In some cases, cities have been made over and their population doubled and trebled by big motor-car factories, as in the case of Flint, Mich., and New Castle, Ind. Such cities have had a tremendous boom in real estate, and in business generally, owing to the influx of 2 000 to 5,000 families, and have assumed an entirely different position on the map because motor-car factories were established within their limits Besides supplying employment to laborers in large numbers, much money has been made by the leaders in the various enterprises. This has been especially true among the makers of wheels tires, frames, and other parts in a general way it may be said that the parts makers have made more money than the automobile builders, as the latter have expended greater sums of money in experimenting

The total capital of the automobile manufacturers in this country is about $225,000,000 The actual value of the plants will run into some extraordinary figures, and these values are rapidly increasing As for the output for 1910, it is likely to exceed 200,000 cars, although there may be a slight falling off from these figures, owing to the inability of parts makers to supply the demand There are now about 150,000 automobiles in use in this country In a general way, it may be said that the employees number some 120,000 in motor car factories with employees in parts factories reaching not less than 40,000, a total of 160,000 America may be safely considered the home of the low-priced car, a condition brought about by the tremendous buying power of the middle classes, who demand a car which can be cared for by the owner without the aid of an expensive chauffeur

These low priced cars have been made possible by ideal factory methods and big production This necessitated their being standardized, something that may be said to be original with the American maker, who feels that any one of ten thousand parts should be made to fit any one car turned out by his company

By working on big productions and

keeping prices down, there is little doubt that the American maker will sooner or later figure in the foreign trade This is particularly true in connection with the small, medium priced car, a field that has been neglected by the foreigners With the rapid growth of the business there have been developed many new captains of industry, who as pioneers have blazed the way for motor-car trade, and who are certain to be important factors in future industrial life

### The Modern Electric Automobile.

(*Continued from page 51*)

current consumption This arrangement is necessary to keep any excessive rush of current at any time away from the battery Nothing is more detrimental to the capacity and the life of the battery A rapid increase of current flow and speed from step to step will result in a jerking action in the whole driving mechanism, which of course means rapid wear and possible breakage of the driving parts It is easier to break a string with a short jerk than with an even smooth pull

The limited power carried in one charge of the battery has forced the designer of electric carriages to avoid as far as possible all losses due to friction in the method of transmission of the power from the motor to the wheels as well as in the bearings. The high-speed motor, with its advantage of light weight and high efficiency in starting and in climbing hills necessitates, in the most approved methods of construction a double reduction of speed This means that the motive power is first transmitted with a reduction of speed to a countershaft, and then to the rear axle. The first reduction of the countershaft is accomplished in different ways and with varying success. The earlier carriages used metal spur gears for this purpose, but they proved to be unsatisfactory on account of their noisy running and great loss of power It may be mentioned here that where there is noise there is friction, and consequently where there is friction there is loss of power The next step of improvement was to make the one gear of compressed rawhide A little less noise in running resulted But this construction was still far from being perfect. After passing through the stages of worm and arrow toothed gears, a perfect transmission was obtained when the Renold silent chain was introduced This chain is self-adjustable to pitch after wear In flexibility and high efficiency, it is an ideal, high-speed transmission device It is found to-day on every high grade electric car If kept in proper alignment and well adjusted the life of this chain is indefinite To receive the best service, it must be dust-proof, incased, and kept well lubricated

The power is transmitted from countershaft to the rear wheels on all up-to-date machines by means of roller chains or through a shaft and bevel gears The advantage of one type over the other has been much disputed The greatest objection to the roller chains is their noisy running, their rapid wear, their exposure to dirt and dust, and their loss in efficiency after wear Some reasons for the superiority of the shaft and bevel gear transmission are its quietness, its cleanliness its long life, and its increased efficiency after use Its durability is due to the fact that the bevel gears run permanently in oil and that they are incased. Moreover, the shaft drive does not require any adjustment, and when well designed, all parts of the running gear and power plant will stay in absolute alignment The necessary adjustment of the double chain drive will soon create a variation in the distance from the front to the rear axle on both sides, for two chains will never stretch alike This disadvantage will affect the steering decrease the life of the tires, and result in a loss of power If the chain sprockets are not in proper alignment after adjustment the chains will rub sidewise on the sprockets, which will, of course, shorten the life of the transmission and result in a loss of efficiency

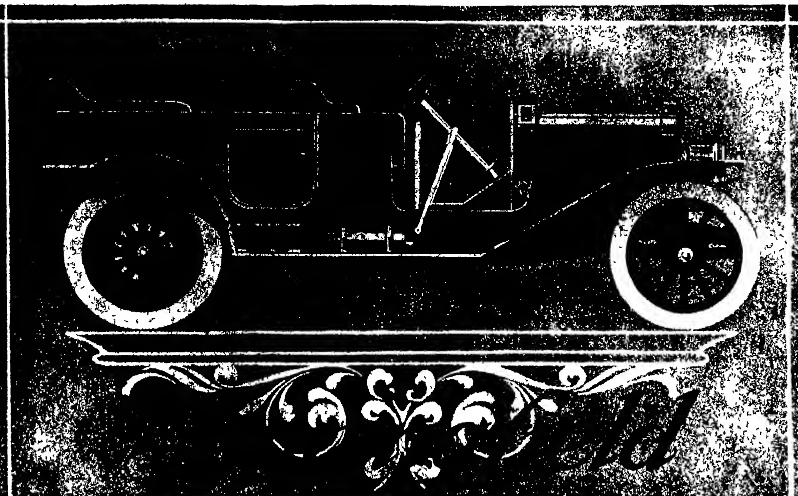
It would be very interesting to measure the distance of both axles on either side of double chain-driven cars after they have been in service in the hands of the average driver and under the care of the average garage for several months to find out if the axles are still parallel Absence of friction is an absolutely necessary factor in the construction of electric automobiles For this reason the proper type of bearings must be applied to the motor, countershaft, and wheels. The ball bearing the highest achievement in bearing construction, has proven to be superior to any other type, and will be found to-day in any high grade automobile Once properly packed with grease this bearing will not require any attention for several thousand miles, if proper sizes for the load to be carried are selected, no wear can be noticed

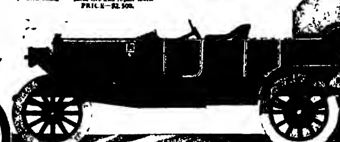
Every electric carriage should be equipped with reliable brakes. It is important that they should stop the car going forward as well as backward It is not the number of brakes with which a car is equipped but their efficiency, which insures safety Most modern cars are equipped with one of two types, namely the external brake in which a steel band surrounds the drum either on the motor shaft or on the rear wheels, or the internal expanding brake attached to the rear wheels, which is commonly used and generally preferred In this construction two brake shoes are fixed inside a drum A small movement of the brake lever will cause the brake shoes to open out against the inside surface of the drum. The braking action should be applied at the rear wheels. All brakes attached to the motor, if used frequently, are detrimental to the motor and the transmission system. For this reason also, the electric brake which seemed in older days to be inseparable from any electric vehicle, is condemned by the modern designer of electric conveyances Even on the heavy electric street car it had to give room, on this account, to the air brake In many brakes the shoes or bands are operated through flexible steel cords, which is not the best arrangement. A system of steel rods is to be preferred In case two brakes are operated by a lever, a balancing bar should be inserted in the system to insure equal pressure on both brakes.

Tires influence the performance of an electric automobile more than may be imagined Various designs of tires show a variation of up to fifty per cent in efficiency, so that the speed per single charge of the battery is affected. Special points to be borne in mind in the care of pneumatic tires are that rust as well as oil is very detrimental to them, and that it is necessary to keep tires well inflated.

If the storage battery of a few years ago be compared with the up to-date battery, it will be found that a very much decreased weight with a large increase in capacity and durability has been obtained

The various wire connections on an electric car should be laid with care, and the wire sizes should be large enough to carry the heaviest possible loads without loss of power As far as possible, all leads should be carried directly from the battery to the controller, and then to the motor, and all connections should be tight and securely locked. One common fault in early cars was the loose hanging wires running in different directions, without any attempt at a methodical arrangement. Good insulation is necessary Because it is able to resist acid, weather, and mechanical strain, rubber of good quality and sufficient size has proven to be the best material for this purpose.





## HOW TO OVERHAUL A CAR

(Continued from page 58)

son for this is that the shafts, especially gear shafts wear down and must be ground true and no manufacturers seem to appreciate the usefulness of boring repair bushings slightly under size The pilot bushing being solid must be specially made to suit the shaft Aside from this one a skillful amateur can make a good job of scraping his own bushings if he has a suitable set of scrapers and time and patience Red lead is used to test the fit Of course the gear case must come out of the car and at intervals the bushing caps are bolted down tight and the shaft turned to determine whether it is tight or free and whether it makes contact all over

In refitting gear shafts and bushings it is necessary not only to achieve a proper fit but to keep the shafts absolutely parallel If they are not the gear teeth will not bear squarely across their face but will wear away at their corners as exaggerated in the dotted portions Fig 4

In the matter of gear replacements the best result is naturally gained by replacing both mating gears if either is badly worn since otherwise the new gear would have to run against a bad profile and would wear away sooner If the car has side chain drive the differential shaft bushings will need refitting at the same time The parts of a differential which wear fastest are the bushings *A* of the spur or bevel pinions *B* (Fig 5) since these are the hardest things to lubricate To take the differential apart it may be necessary to file the ends of headed over through bolts holding it together In that case the nuts should be reduced in thickness so that the bolts can be headed over again on reassembling (The bolts in Fig 5 do not go through) It is very important not to give anything about the differential the slightest chance of working loose and the same applies to the bolts holding the change gears Another point that is difficult to oil and therefore liable to cut is the bearing *C* between the differential or gear hub and the sleeve into which the hub of the differential shell extends This sleeve runs in plain or ball bearings in the case with the shaft or gear hub turning inside of it whenever the car goes around a turn Sooner or later new bushings are needed

If oil is used in the gear case as it must be if plain bushings are used instead of ball bearings it becomes something of a problem to lubricate the bearings effectively without excessive leakage of oil The writer solders a thin wire gauze screen (Fig 6) over the interior oil pockets to exclude steel grit worn from the gears In order to prevent escape of oil from the ends of the bushings a felt ring is necessary (Fig 6) This ring would cause the oil near it to become stagnant were it not for a special oil groove *B* which should be chipped entirely around the bushing and connect with a groove *C* by which oil entering it may return to the interior of the case But for this provision particles of dirt getting into the end of the bearing would accumulate and cut the shaft

In the rear axle of a shaft-driven car the thing most likely to need replacement is the differential There are various ways of getting at it depending on the design of the axle casing If the axle is divided vertically in the fore and aft central plane the rear springs must be jacked up and disconnected from the axle and the halves of the axle drawn asunder after taking off the wheels A better arrangement is to have a removable cover plate on the casing through which the differential is inserted and withdrawn This is found especially in axles of the floating type with wheels running on ball or roller bearings on the ends of the axle tubes and driven by floating shafts extending from the differential to jaw clutch plates engaging the outer ends of the wheel hubs To remove the differential the hub caps are first removed and the floating shafts slipped out from the differential without jacking up; then the straps holding down the differential are removed, the bevel driving pinion withdrawn, and the differential lifted out.

Unless a car is more than one year old it is not necessary to assume that the differential needs overhauling. By jacking up one rear wheel and rocking it back and forth, the total amount of slack in the differential may be estimated. It is also usually possible to reach the pinions through openings in the differential shell, and by shaking them to determine whether they are loose. If so, they should be rebushed and the pins or spider replaced if worn. Frequently means are provided for advancing slightly the driving pinion or gear or both to compensate for wear If this adjustment is disturbed the gears should be moved in a straight line and not canted around, else the teeth will engage only at their small or large ends instead of over their full length By rubbing red lead on the teeth and turning the gears, one can tell where the teeth touch

If cup and cone ball bearings are used whether in the rear axle or in the transmission any worn parts should be renewed immediately Fig 7 shows the effect of wear on a stationary ball cone, e g on an axle spindle The pressure comes against the stationary bottom portion and while the cup wears a true path the cone is destroyed It is possible though not always worth while to prolong the life of the cone by giving it a quarter or half turn on the shaft or axle If the cup is stationary and the cone rotates evidently the cup will be the first to wear out of round When one ball of a set is renewed the entire set should be replaced with it

We come now to the engine the last and in some ways the most difficult part to overhaul The owner is strongly advised not to attempt to refit the main crank shaft bearings unless he has had considerable previous experience and knows exactly what to do On the other hand it is not at all hard to regrind and readjust valves replace worn valve lifters and their guides and to do ordinary tinkering and adjusting with the timer carbureter etc It is best not to tamper with the magneto further than to clean the interrupter and adjust the interrupter contact points if worn

To overhaul the engine first strip it of all small gear Take off the magneto first marking the coupling so that it can be replaced exactly as it was, and tag the wires Remove and tag the oil pipes, blow through them to see that they are clear and plug them to exclude dirt Disconnect the carbureter remove the timer take out the spark plugs and plug the holes with waste remove the dust pan take out and mark the valves take off the water pipes, the pump, and the fan Now take off the cylinders If no further dismantling is contemplated the piston heads may be scraped *in situ* taking care that none of the carbon falls into the crank case and the piston rings are likewise cleaned without removal if possible If the rings are leaky as proved by failure to hold compression when the valves are tight new rings are put in and fitted to the locating pins which prevent them from turning At the same time the carbon can be scraped from the inside of the cylinder heads.

Take down the oil pan Test the fit of the wrist pin and crank pin bearings by rocking the pistons and connecting rods on the pins. Do not confuse a rocking motion due to loose fit with end play on the pins A certain amount of end play is always provided A crank pin bushing is likely to wear conical (see shaded area) if the rod is offset as in Fig. 8, and if the rod is springy the bushing may wear bell mouthed at both ends. The crank pin itself will in time wear flat at the point of greatest pressure, as indicated in Fig. 9 It takes more skill than can be acquired off-hand to true it up again, but it can be done with a fine

Swiss file and calipers. It is not necessary to file clear around the unworn portion of the pin, since a slight deviation from its original axis does no harm, neither is it absolutely essential that it should have the same diameter throughout. Its new axis, however, must be absolutely parallel to the shaft It is best to throw away worn bushings and put in new, taking out or inserting shims till a fit is obtained, and scraping no more than is necessary A worn wrist pin bushing must be renewed, and usually the wrist pin must be ground true If the crank pins are oiled through passages drilled in the crank shaft, their lubrication is probably perfect. If, however, they are oiled solely by splash and the oil holes are in the upper half of the crank pin bushing, a considerable improvement can be made by replacing the upper bushings with solid ones and introducing the oil through the bottom half by brazing a copper tube in the cap to act as an oil scoop (Fig 10) The bottom half is then drilled and provided with an oil groove for about half its length It is a principle of lubrication that the oil should always be introduced at the unloaded side of the journal and that any breaks in the continuity of the loaded surface merely afford the oil an avenue of escape under pressure

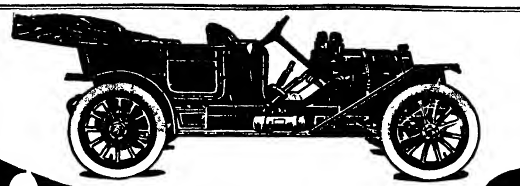
To renew the clutch leather, take off the old leather and use it as a pattern Select the new leather carefully for uniform and correct thickness, and cut it about half an inch short The curvature should be approximately that of the old piece (Fig 11) Locate the end and the middle holes for the rivets countersinking them considerably so the rivet heads will not come flush, and soak the strip in water till it has swelled sufficiently to go in place Use the end of a steel bar as an anvil, and put in the end and middle rivets first, holding the strip meanwhile by wire nails The riveting must be completed before the strip dries.

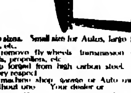
### AUTOMOBILE FIRE-ENGINES.

(Continued from page 55 )

fire engine proper After reaching the scene of the fire the driving gear is uncoupled and the pumps are put in connection with the engines. Such fire engines of course must draw their water from a hydrant, well, or other supply They have done splendid work in suburbs wherever fire engines of suitable power or an adequate high-pressure system can be held in reserve The best of those machines can run to a fire with a crew of seven men at speeds up to 60 miles per hour and carry 1,000 feet of hose The pumps deliver 700 gallons of water per minute at pressures up to 150 pounds to the square inch The regular steam fire engine has a capacity varying from 400 gallons per minute to 1,000 gallons in the case of the largest size of machines. Such a motor fire engine usually contains two 3-gallon chemical extinguishers, and heavy suction hose for hydrant connection, fire axes, nozzle holders, large alarm bell, the usual equipment of lamps, lanterns, tools, and small scaling ladders. In the opinion of many fire engineers a suburban fire station should have two such motor engines, with possibly a steam engine in reserve Again, steam engines may also be held at reserve stations instead of a large number of single steamers. This means considerable economy in the purchase, equipment, and maintenance of a fire house, while the increased radius of action and the speed of the motors enable efficient service to be rendered.

Finally, we may consider machines in which no essential change is made in their construction except to use the gasoline motor and means of propulsion in place of the usual horses. Typical of these are the large combination hose wagons and chemical engines which carry 1,000 feet of 2½-inch fire hose and answer every purpose of the horse-drawn wagons which they are destined to supplant. Fuel for 150 miles can be carried in the gasoline tanks and speeds





up to 30 and 35 miles an hour with full load are easily achieved To carry the heavy hose for the high pressure service of New York city a special automobile wagon has been found most useful and in over a year of service has met every test Put into use in January, 1909, it was successfully operated on snowy and slippery streets and never failed in responding to an alarm This vehicle is built to run up to 30 miles an hour on city streets climb any reasonable grades, and to carry the full strength of a high-pressure company It carries forty 50-foot lengths of 3 inch heavy rubber high pressure fire hose and has a turret nozzle mounted upon the drivers seat from which a powerful siamesed stream can be delivered It takes the place of a three-horse wagon previously employed In fact this automobile truck of New York city has been the logical outcome of the high pressure service in the lower part of Manhattan The future will probably see it extensively used in New York and in other cities provided with high-pressure service

Nor is the use of the automobile confined to the emergency wagons chemical engines combination and hose wagons Aerial ladder trucks up to 85 feet in height are now made for motor traffic and have all the essential features of this important piece of apparatus previously requiring three horses A useful aerial motor truck is mounted upon a 90 horse power four-cylinder automobile the automobile taking the place of the forward wheels thus making a six wheel vehicle slightly longer than the ordinary ladder truck with its horses, but steered by a tiller wheel in the rear in the same manner The whole machine can be turned in its length around corners and is often more easily controlled and regulated than with horses besides being capable of running 25 miles per hour with full equipment and crew on a five per cent grade This apparatus is of interest in comparison with the somewhat shorter ladder devices known as "escapes" which are in use in Europe and which have been developed there to considerable efficiency

That the motor-propelled apparatus is bound to come eventually and to supplant horse-drawn machines seems to be the opinion of progressive fire fighters. Chief Croker spoke in this vein to the writer and said that it was only a matter of expense in the original outlay that prevented motor fire engines from being extensively adopted in the suburbs of the greater city In fact during the last weeks of the past year the Fire Commissioner advertised for bids for furnishing two automobile combination gasoline engines and hose wagons for the borough of Brooklyn and one for the borough of Queens. At present the high efficiency motor fire engines cost more than steam fire engines of greater power, and as fire-fighting power is desired first of all, in nearly every large city department, the chiefs prefer heavy units to increased mobility and speed On the other hand the makers of motor fire apparatus claim that the economies of maintenance more than justify the increased expense

There are several questions that enter into the operation of commercial motor vehicles that naturally arise in connection with fire apparatus. One is, the matter of tires, but it must be recalled that the actual mileage of fire apparatus is inconsiderable and that furthermore the best fire vehicles are now supplied with rubber tires, so that there would be no more wear in one case than in the other Fire engines, owing to their portability and the speed with which they must be brought to full working capacity, are notoriously inefficient machines from a mechanical standpoint, and the gasoline engine in no way works for worse conditions. If reasonable economy of operation is secured as well as reliability of service, then with the extraordinary decrease in the cost of maintenance the gasoline motor-driven machine is bound to have a successful future

### ANTI JOY RIDE DEVICES.

(Continued from page 58.)

other parts of the car by means of attachments fastened inside the hood For example by means of two thumbscrews through the dash, which are inaccessible until the hood is raised, the footboards can be secured against removal, and this will make it impossible to open the cover of the gear box Furthermore, there is combined with the lock a vibration indicator to record movements of the vehicle

Every precaution to render the device proof against tampering seems to have been taken by the inventor, who asserts that it is impossible to start the engine, open the hood, or operate the car without the owner's knowledge or consent unless he has forgotten to withdraw the key or has given a duplicate key into the possession of the chauffeur. In the latter event the chauffeur cannot take the car out on the road without having the approximate distance traveled registered by the vibration recorder

The only visible part of the device is a polished brass plate 2 by 4 inches in size which is set into the dash. In the upper part of this is set a casting containing a compact switch for use with any system of ignition and also a Yale lock provided on its inner end with a cam plate and contact piece. The lock key takes the place of the usual switch lever, and the switch cannot be operated without it. It is also impossible to remove the key until the switch has been turned to "off" position.

Two bell-crank levers surrounding the barrel of the Yale lock behind the switch are operated by the cam plate of the lock, and their long arms are attached to small steel cables that pass through eyelets screwed into the dash under the hood These cables lead to two special spring latches secured to the lower inner corners of the dash in a position to engage the slots cut in strips of angle iron riveted to the inside of the hood on either side. Thus, when the key and cam are in open position, as shown in the drawing, the latches are withdrawn and the hood can be raised, but when the switch has been turned to "off" and the key removed, the latches are released and hold the hood against all attempts to raise it. The engines may be run with the hood open, and the hood will lock automatically when closed

In a special recess directly beneath the Yale lock is placed a vibration recorder, resembling a pedometer in appearance and action, which is held securely by a plate provided with a spring to press against the back of the instrument. The vibration recorder is so adjusted that it will not be affected by the running of the engine while the car is at rest, but will record the vibrations of the car when in motion The plate is sealed by a wire and lead seal and also by a strip of paper pasted across the back with the owner's name written thereon, and if these seals are broken explanations from the chauffeur are in order, as he is the only person except the owner who has access to the hood chamber. The switch can be removed without disturbing the sealed chamber holding the recorder, but only after the hood has been raised. It is impossible to remove any part of the mechanism from the exposed side of the dash.

### MAKING YOUR OWN REPAIRS.

(Continued from page [illegible].)

graphite, and in order to apply it, the springs must be relieved of the weight of the car To do this, apply jacks to the corners of the frame, and operate them until the tires are clear of the ground. The weight of the axles and wheels will

(Continued on page 7[illegible].)

*(Continued from page 70.)*

then be suspended from the springs, and in almost all cases it will cause the leaves to separate sufficiently to permit the lubricant to be introduced by means of a thin bladded table knife

CLEANING THE OILING SYSTEM

It occasionally happens that the oiling system becomes clogged, either from the thickening of the oil or the introduction of dirt and grit.

In the majority of cases this may be cleared away by draining the oil from the tank and crank case, putting a pint or two of gasoline into the tank, and cranking the engine briskly The gasoline will thus be forced through all parts of the system, and will cut out the thick oil and dirt Before refilling the tank with oil, the gasoline should be drained out and time allowed for it to drip out of the piping

CUTTING A GASKET

To prevent the leakage of oil the cover of a gear case usually rests on a gasket, which may easily be injured or destroyed when the cover is removed. Its shape makes it seem a difficult part to replace, but as a matter of fact it is a question of only a *few* minutes work to replace it

The material to use is smooth and uncreased brown wrapping paper of medium weight, and of a surface that is not too highly glazed Clean the top of the gear box and lay the paper over it, then with a light hammer tap the paper where it rests on the outer edge of the flat part The edge cuts through the paper where the hammer strikes, and to get the gasket to proper shape it is only necessary to follow the edge all around To prevent the slipping of the paper, the first step might well be to cut two bolt holes through it, and to insert the bolts The holes are cut by striking the paper over the bolt holes in the gear case, using the ball end of the hammer

The inside opening is cut in the same manner as the outside Before applying the gasket, give one side a coat of red lead and the other a coat of shellac, and in placing it in position have the shellac side down, or in contact with the stationary part The gasket will then cling and will not be torn on any subsequent removal of the cover

A gasket made in this way will give excellent results under the detachable head of a marine or stationary engine, but after fitting it the engine should be run sufficiently to get normally heated before finally setting up the nuts or bolts that secure the head to the cylinder

TO REMOVE A DENT

Aside from its unsightliness, a dent in a tube, radiator housing or other metal part may interfere with operation, and it becomes necessary to remove it To do this form one end of a piece of stout copper wire into a loop, and solder it to the lowest point of the dent. Then exert a strong and steady pull on the wire, at the same time tapping the borders of the dent with a light hammer When the dent is thus pulled out the solder may be melted off and the finish restored with fine emery and crocus cloth.

A dent in a gasoline tank is more difficult to remove on account of the greater stiffness of the metal, but it may be accomplished by the use of a discarded valve Clean the valve head with emery cloth and solder it, not to the bottom of the dent, but to one of the sloping sides. The valve stem then forms a sort of lever by which the dent may be pried out

REPAIRING A SPLIT TUBE.

The copper and brass piping used for gasoline and water connections has a tendency to split, and an injury of this sort apparently calls for a renewal of the part. This, however, is not always necessary, for a permanent and sightly repair is a comparatively simple matter. The work is begun by winding No 14 soft copper wire around the split portion of the pipe, and a half-inch beyond each end. Then, after heating and applying soldering solution, the windings should be soldered together and the outside windings soldered to the tube. This will form a tight jacket around the split portion of the tube, and will save the very considerable expense of a new part.

LINING UP THE WHEELS.

While it is not generally realized, yet it is none the less true that the failure of tires to give good service is in many cases due to the wheels being out of line. This may be caused by misadjustment, sprung steering-rod or arms, a twist in the axle from road shocks, all of which result in throwing the wheels out of parallel with the center line of the car If the wheels are set correctly, they will have a true rolling motion on the road, and the slightest deviation from this position will set up an additional sliding action that is destructive to the tire surfaces.

In testing the parallelism of the wheels it may be taken for granted that the side members of the frame, as well as the springs, are parallel Starting with a rear wheel, measurements should be made of the distances between the spring and the forward and rear portions of the felloe, at points as nearly as possible on the level of the axle These measurements should be equal, and should be the same as corresponding measurements made on the opposite side of the car If the figures indicate that the wheels are equally out of parallel with the springs, matters may be set right by making a proper adjustment of the radius rods.

To test the front wheels, manipulate the steering gear until measurements show one wheel to be parallel to its spring, it will be necessary to adjust the drag link, which is the bar connecting the steering arms of the two knuckles.

Another method of testing the wheels is to stretch a string along the sides of a front and rear wheel, just above the axle. With the steering gear set for straight running the string should touch each wheel at two points, as indicated in the diagram If the wheels are not true, the string will touch at one point only, as illustrated

LOCATING ENGINE NOISES

The writer was once called on to locate a knock in an automobile engine belonging to a doctor There was no question as to the cylinder, nevertheless even the use of a stiff wire, one end held in the teeth and the other resting against the engine, failed to determine whether the trouble was in the crank pin or wrist pin.

The sight of a stethoscope in the doctor's pocket suggested its use, and the knock was immediately located in the wrist pin. A stethoscope now takes an important place in the writer's testing equipment, and he believes that it will be found invaluable in the repair shop By its use looseness in a bearing may be detected long before it becomes serious, escaping gases may be heard hissing past worn piston rings or pitted valves, and other noises that indicate slight faults are brought to the attention of an intelligent user

TIMING MAKE-AND-BREAK IGNITERS.

Under usual conditions it is difficult to time igniters with any degree of accuracy, but it may be accomplished with surprising ease by the use of an electric bell, a battery and wire. One side of the battery is to be grounded, the other connected to the bell, and the circuit continued to the insulated part of the igniter, as shown in the diagram. When the igniter is not making contact the bell circuit is open, but when the piston is moving on a compression stroke the igniter makes contact, and the bell rings.

When the spark control lever is in the retarded position, the igniter should break contact when the piston reaches the top center of the compression stroke. To make the adjustment, crank the en-

*(Concluded on page 74.)*

# A Wonderful Business Story

**We have told in a book—which we ask you to send for—one of the greatest business stories ever told. A story of how John N. Willys stepped in two years to the topmost place in motordom. Of how *Overland* automobiles rose in 24 months to this year's sale of $24,000,000. How a factory has grown like magic to a payroll of 4,000 men—to a daily output of 30 carloads of automobiles. And how a large part of the demand of the country has been centered around one remarkable car.**

## The Discovery

Here is an outline of the story—just enough to make you want it all

Two years ago, Mr John N Willys was a dealer in automobiles There came to him one day a remarkable car—evidently the creation of a mechanical genius. The simplest, sturdiest, smoothest-running car that anyone around there had seen

The name of the car was the Overland And the price—then $1,250—was as amazing as the car itself

The sale of this car spread like wildfire Each car sold brought a call for twenty others like it. Old and new motor car owners came by the score to deposit advance money—attracted by the Overland's matchless simplicity

But the cars did not come And when Mr Willys went to the makers he found them on the verge of receivership.

The genius which had created this marvelous car could not finance the making, in the face of the 1907 panic.

## The New Start

Mr Willys in some way met the overdue pay roll—took over the plant—and contrived to fill his customers' orders.

Then the cry came for more cars from every place where an Overland had been sold. As the new cars went out the demand became overwhelming. The factory capacity was outgrown in short order. Then tents were erected.

Another factory was acquired, then another, but the demand soon outgrew all three.

During the next fiscal year these factories sent out 4,075 Overland cars. Yet the demand was not half supplied.

Dealers fairly fought for preference. Buyers paid premiums. None could be content with a lesser car when he once saw the Overland

All this without advertising. About the only advertising the car ever had was what users told others

## The Pope-Toledo Plant

Mr. Willys' next step was to buy the Pope-Toledo factory—one of the greatest automobile plants in the country This gave him four well-equipped factories—just 16 months from his start.

But the Toledo plant wasn't sufficient So he gave his builders just 40 days to complete an addition larger than the original factory

Then he equipped these buildings with the most modern machinery—with every conceivable help and convenience—so that cars could be built here for less than anywhere else

Now 4,000 men work on Overland cars The output is valued at $140,000 per day The contracts from dealers for this season's delivery call for 20,000 cars

Now this man has acquired 23 acres around his Toledo plant And his purpose is to see—from this time on—that those who want Overlands get them

## Marvelous Sales

Dealers had ordered 16,000 of the 1910 Overland models before the first car was delivered. That means that each Overland sold the previous year had sold four others like it.

And without any advertising.

This year's Overland sales will exceed $24,000,000. Yet the Overland is but two years old.

## The $1,000 Overland

This year an Overland—better than last year's $1,250 car—is being sold for $1,000 That is because the tremendous production has cut the cost 20 per cent.

A 25 horse-power car, capable of 50 miles an hour, for $1,000, complete with lamps and magneto Never did a maker give nearly so much for the money.

There are higher-powered Overlands for $1,250—$1,400—$1,500 They are just as cheap in comparison as the $1,000 model

The Overlands are unique in simplicity They operate by pedal control A ten-year-old child can master the car in a moment

They are made in the same factory, and by the same men as made the Pope-Toledo—a $4,250 car The reason for the price lies in the production of 125 cars per day

## Get the Whole Story

Send me this coupon to get the whole story, told in a fascinating book Learn about the car which in two years captured so large a share of the whole trade of the country See what has done this—what there is in the Overland to make it the most desired car in existence Please cut out this coupon now.

(Concluded from page 72.)

gine until the piston is in this position, and then adjust the tappet until the igniter just breaks contact and the bell stops ringing. To test, crank the engine until the piston again makes a compression stroke and the bell begins to ring. Continue to crank, proceeding slowly, and observing the position of the piston by means of a wire passing through a relief cock, or by marks on the flywheel. The bell should stop ringing at the instant when the piston reaches its topmost point.

LACING A FAN BELT.

The requisites for joining together the ends of a flat lacer belt are rawhide lacing $\frac{1}{4}$ or $\frac{5}{16}$ inch wide and a round punch of such size that it will cut a hole in which the lacing will make a snug fit. For a fan belt of average width three holes may be punched in each end, the outside holes $\frac{3}{8}$ inch from the end and the center one $\frac{1}{2}$ or $\frac{3}{4}$ inch in, the holes in the two ends being in line. The relative positions of the holes are shown in the diagram. The lacing is passed through the holes in the manner indicated and drawn tight. To secure the end a cut is made on each edge of the lacing, extending inwardly for one-quarter of the width, the knife being laid flat on the belt. The lacing is cut off $\frac{1}{2}$ inch farther up. The end may then be flattened out, and the wings formed by cuts will prevent it from pulling through the hole.

The belt will stay in position only when the stitches in contact with the pulley are parallel to the pulley edge. If the belt is placed on the pulley so that the slanting stitches are in contact with the pulley face it will tend to ride off.

In an emergency heavy wire picture cord of the ordinary stranded variety may be used in place of rawhide. The only objection to its use is the click that it makes in coming in contact with the pulley.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

RECEPTACLE FOR BABY CLOTHS.—C. Haskwell, New York, N. Y. The invention provides a receptacle for baby cloths and other articles of wear offensive for manual handling in which the washing may be performed; provides for operating the receptacle in the bowl of a water closet, utilizing the flushing water of the bowl, and wherefrom the water may be drained from the bowl; provides holding devices for the receptacle to retain the same in operating position; provides for flushing water in the bowl and means for preventing flooding of the bowl to overflow the same.

### Of Interest to Farmers.

COTTON PICKER.—G. Sickel, St. Joseph, Mo. The objects of the inventor are to provide a mechanical contrivance for picking cotton, a device for mechanically controlling the cotton as picked, and a mechanism which will perform its functions without damage to the growing plants and to lessen the labor incident to picking by hand.

WEED EXTERMINATOR.—E. A. Francis, Marshalltown, Iowa. The intention here is to provide a device compact in form, so that it can be easily carried about by the operator, and which is so constructed that the mechanism whereby the liquid is discharged from the body will not become clogged by dirt as the lower end of the body is forced into the ground.

AUTOMATIC FOWL-DUSTER.—O. E. Ruffum, Enumclaw, Wash. The invention has for its object a duster in which the container for the dusting material is movably mounted and driven by the frictional contact of the fowl in passing under it, the container being adjustable to different elevations to suit fowls of varying heights.

TRIP MECHANISM FOR CORN PLANTERS.—H. F. Hermanson, Alcester, S. D. The purpose of the invention is to provide an improved trip mechanism, especially adapted for use with corn planters, but capable of use in any device where it is desirable to operate one part intermittently by means of a continuously moving part.

### Of General Interest.

REINFORCED CONCRETE CONSTRUCTION.—A. H. Schmerbacher, Winnipeg, Manitoba, Canada. The improvement refers to reinforced concrete construction, and the object is to provide a simple construction in which the metal reinforcing parts are connected in a manner so as to form an efficient reinforcing skeleton for concrete walls, floors and similar constructions.

BRACE FOR BRICK KILNS.—A. Prauss, Kingston, N. Y. In this case the object is to provide a brace which is adapted to brace the sides of a brick-kiln to serve as a support while the bricks are being baked. The brace is adjustable so that it may be fitted between a side of the kiln and a framing spaced therefrom, without endangering the workmen in charge of the work.

LOOSE-LEAF BINDER POST.—F. H. Crump, Los Angeles, Cal. The posts are provided with a head which will so engage the top binder plate as not to protrude through it. The bolt (male and female) will remain together when the top cover has been removed. The post is for use with a round hole sheet, which will not come off the post though held loosely between the covers.

SCALE.—C. M. Sturgis, Birmingham, Ala. The principal objects here are to provide a structure which may be readily extended, a structure wherein the moving parts are securely and simply mounted, a structure having a multiplicity of carrying beams with a single adjusting member, one wherein the platform may be supported upon end rails without interfering with the moving parts of the scale proper.

LOOSE-LEAF BINDER.—J. M. Lull, Wausau, Wis. The invention relates to a special form of binder for holding the sheets of loose leaf books. The patentee provides for each group of leaves a novel form of clamping plates having specially designed interlocking lugs that clamp the plates together and engage the leaves of the book.

### Hardware.

WINDOW LOCK.—I. C. Scudder, New York, N. Y. The invention relates to certain improvements in window locks, and more particularly in a locking device adapted to be detachably secured to the lower portion of the upper sash to limit the extent to which this sash may be lowered or the lower sash raised.

JACK.—W. B. McCain, Clearlake, Wash. The jack in this improvement is of the double action type and in operation lifts the load step by step or lowers it in like manner according to the relative disposition of certain parts, and it is provided with means for entirely releasing the lifting bar whereby the latter may drop instantly to initial position.

HASP-FASTENER.—H. L. Lambrecht, Sullivan, Ill. The invention is an improvement in hasp fasteners, and has for its object a construction in which the latch bolt is automatically engaged in a notch or recess in the keeper when the hasp is swung to locking position, thus preventing the withdrawal of the hasp until the latch bolt is retracted.

PITCH BOARD.—C. E. Little, St. Joseph, Mo. This measuring instrument is more especially designed for use by carpenters to enable them to accurately obtain the length and bevels of rafters, thus enabling a carpenter to frame the roof of a building with ease and dispatch and without the use of a square or a bevel and without requiring mental calculations.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 18th or will be sent by mail on request.

(12168) J. R. U. says: 1. Could you tell me the supposed speed of Arcturus per minute and its probable distance from the north star? A. It is difficult to give a velocity for Arcturus. The researches of Prof. Elkins some years ago are fully reported in our SUPPLEMENT No. 909, price ten cents. These tend to make us believe that the velocity of Arcturus is very high, about 380 miles a second, and its distance from the earth about 180 light years. The approach of Arcturus toward the earth is about 53 miles per second. These researches were published nearly twenty years ago, yet there are no later determinations, and they are the ones given in our textbooks of astronomy. We do not know its probable distance from the north star. Probably that has not been determined. 2. Is the north star the center of attraction around which the circumpolar constellations move? A. The north star is simply the star which at present happens to be nearly in the line of the earth's axis prolonged to the celestial sphere. As the earth's axis is in motion around the pole of the ecliptic, the pole will move away from the present pole star and will not return to its present position till 25 000 years have passed. The pole star is not a center of attraction in any sense. It is simply a pole star to the earth at the present time, and the constellations seem to move around it as seen from the earth and not as seen from other stars.

(12169) G. F. B. says: I would like

to secure a book giving a complete course of experiments in physics for the first year in high school. It is especially in electricity I would like a course, beginning at the very bottom and working up by simple and readily intelligible experiments. Have you such a book, or can one be procured from some of the large book supply houses? A. We recommend and can supply you with Carhart and Chute's "High School Physics," for $1.35 postpaid, and also Chute's "Laboratory Manual of Physics," for 90 cents postpaid. With these you will be equipped for learning the work in elementary physics up to the entrance to college. The work is graded just as you request, and is just what is done by everyone fitting for college in the United States to-day.

(12170) J. S. says: 1. What is the exact length of a sidereal and a tropical year? A. The sidereal year is in mean solar time 365 days, 6 hours, 9 minutes, 8.97 seconds. The tropical year is in mean solar time 365 days, 5 hours, 48 minutes, 45.51 seconds. These are not exact, but are correct within a hundredth of a second. 2. What do you hold of water witching? Do you think a person can locate water in the ground with the aid of a forked switch? A. We do not "hold" anything about "water witching." We do not believe that water can be located underground by a stick.

(12171) A. J. H. says: Some time ago you had an explanation published in your SCIENTIFIC AMERICAN of how a square of 64 inches on changing the angles became an oblong with 65 squares. Please advise me how this is done and where the fallacy comes in. A. You will find the explanation of the fallacy of the cardboard square, cut to appear to increase one square inch in area, in our Notes and Queries of Vol. 99, No. 21, which we send for ten cents. The article occupies more than a column and is illustrated by drawings to scale.

(12172) H. C. A. says: What is the chemical symbol for litmus? How is litmus paper made? Why do the acid and alkali have the property of changing the color of it? A. Litmus is a natural dyestuff of unknown chemical structure. Doubtless one of its colors is that of the molecule, the other that of its ion. Litmus paper is made by preparing a solution of litmus in water, soaking filter paper in the solution, and allowing it to dry. If red litmus paper is desired, the solution is reddened by a drop of an acid before the paper is dipped into it.

(12173) E. R. S. says: Please decide this question and oblige a subscriber. A states that in sending a message by telephone the transmitter vibrates, and this vibration travels over the wire by an electric current. B states that when the transmitter and receiver are fully connected between given points of any distance, that space is eliminated in the sending of a message, therefore no travel is necessary or time consumed. A. If we understand your statements, neither A nor B is wholly right. We should state the action of the telephone in this way: When the diaphragm of a transmitter vibrates, the variation of pressure upon the carbon particles in the transmitter causes an undulation in the current from the transmitter to the receiver at the other end of the line. In this receiver an undulation is produced of the same period as that in the transmitter; this causes a vibration of the diaphragm of the receiver, which is heard as a sound by the person who is receiving the message. Along the line a varying electric current flows; there is only an electric current along the line. There is sound at both ends. The same time is required for the impulse to travel from transmitter to receiver as would be required for a telegraph signal to travel over the same wire to the same distance.

## NEW BOOKS, ETC.

EXTRACTS AND PERFUMES. By Wilbur L. Scoville, Ph.G. Boston: The Spatula Publishing Company. 16mo., 101 pp. Price, $1.

This is a valuable treatise on the most practical methods for the manufacture by the retail or wholesale pharmacist of flavoring extracts, colognes, toilet waters, perfumes, sachets, fumigating pastilles, etc. It is an excellent book on the subject.

THE PREVENTION OF INDUSTRIAL ACCIDENTS. By Frank E. Law, M.E., and William Newell, A.B., M.E. New York: The Fidelity and Casualty Company of New York, 1909. 16mo., 194 pp. Price, 25 cents.

The prevention of industrial accidents is one of the most important subjects which have come to the fore in the opening years of the present century. The American Museum of Safety and Sanitation has obtained a more or less secure foothold in the counsels of great manufacturers and great industrialists are to be found on its board of trustees. Strange to say, the insurance companies, instead of being antagonistic, have done everything in their power to support and promote this movement, and they have, may it be said to their credit, contributed much of the sinews of war to the organization referred to and to similar enterprises. The position of the SCIENTIFIC AMERICAN as regards the

prevention of industrial accidents is indicated by the fact that this journal offered a prize, a handsome gold medal, for the best device for safe guarding life and limb, and this medal is awarded annually when there is a competition held by the American Museum of Safety and Sanitation The small pamphlet before us is filled with information of the greatest possible value, and it is truly a "life saver"

HOLLAND OF TO-DAY By George Wharton Edwards. New York Moffat Yard & Co., 1909 8vo., 217 pp Price $6

It is a pleasure to look through this splendidly made book, in which the author artist and the publisher have collaborated to produce a *chef d'oeuvre* Mr Edwards is an accomplished master of line and a brilliant colorist and the somewhat gaudy tints of a Holland costume and landscape are brought into their proper key in the splendidly colored illustrations with which the book is embellished To those who know their Holland well this book is a great treat, while it is especially commended to those who are unfamiliar with this tight little country, and to whom it will serve as an excellent guide The text is a matter-of fact description of what the traveler may find in Holland today, and he will glean many interesting facts such as the plurality of cheeses at breakfast, the growth of tulips, and information as to the head dresses of Friesland The illustrations showing old Dutch silver are particularly valuable The binding is most sumptuous

THE SPATULA LABEL BOOK By Wilbur L. Scoville, Ph G Boston The Spatula Publishing Company Price, $1

This valuable book is indispensable to the druggists comprising labels for practically all the drugs chemicals and preparations of the United States Pharmacopoeia and the National Formulary, together with many for drugs in the British Pharmacopoeia, and for a large number of unofficial articles, utensils, apparatus, etc In all over 2,000 labels. These labels are printed in large type on paper which is easily pasted on bottles, drawers, etc. It is worthy of a considerable distribution

TIME AND ITS MEASUREMENTS By James Arthur Chicago Popular Mechanics, 1909 8vo., 64 pp Price, $1 50

This rather interesting book describes ancient methods of keeping time Japanese clocks modern clocks, and the astronomical foundation of time It gives a considerable amount of information not readily obtainable elsewhere

HAND BOOK OF BRITISH GUIANA 1909 Edited and compiled by George E Bayley of the British Guiana Civil Service Georgetown, Demerara, British Guiana 8vo., 607 pp Price, $2

This portly volume describes everything which anybody would possibly want to know about British Guiana, and is a most creditable work on a most beautiful and interesting country

## INDEX OF INVENTIONS

**For which Letters Patent of the United States were issued for the Week Ending January 4, 1910.**

**AND EACH BEARING THAT DATE**

[See note at end of list about copies of these patents.]

Adjustable bracket, J. H. Lindberg ... 945,380
Aerial machine, W P Goble ... 945,514
Agricultural implement, Hoover & Gates ... 945,560
Agricultural implement tool controlling mechanism for W H Rice ... 945 192
Air brake automatic W A Turner ... 945,063
Air pressure indicator, H W & G H Brown ... 945 216
Air switch C F Presler ... 945 416
Alarm apparatus switch mechanism for electrical A A Strait ... 945 684
Amalgamator C H Hotchkiss ... 945 539
Ammonia from gas, obtaining H Koppers ... 945,882
Amusement purposes, pit for, H N Ridgway ... 945 604
Anchor H. Fuchs ... 945 269
Antisiphon trap G W Smith ... 945 428
Antiskidding device, R D Stimpson ... 945 637
Apron and overalls combination J. E Richards ... 945 345
Ash sprinkler D. Block ... 945 182

Abrasives, F. O. Dermant ... 945,[illegible]
Audiphone receiver, G. R. Williams ... 945,[illegible]
Audiphone transmitter, portable, G. R. Williams ... 945,[illegible]
Auger, expansion, J. W. Caldwell ... 945,016
Auger handle, G. W. Foreman ... 945,[illegible]
Automobile, O. Berg ... 945,[illegible]
Automobiles and the like, mechanism of, horns for, L. A. Boutonnet ... 945,[illegible]
Awning, H. Smith ... 945,[illegible]
Axle, W M. Nash ... 945,184
Axles, device for laying off wooden, G. W Golding ... 945,515
Bag. See Feed bag.
Bag holder, F O. Vanderzee, Jr ... 945,[illegible]
Bag or purse frame, H. R. Nock ... 945,[illegible]
Balance, specific gravity, R. R. Jolly ... 945,[illegible]
Baling press, J. E. Tuttle ... 945,114
Ball and like game, base, F F Garbarino ... 945,511
Bank, savings, F Rhode ... 945,606
Bar See Draw-bar; grate-bar
Basket handling machine, F L. Haberle ... 945,521
Bath tub R. F Williams ... 945,[illegible]
Battery cells, mechanical construction of storage, P Kennedy ... 945,[illegible]
Bearing, conical pivot, A F Fletcher ... 945 712
Bed, invalid, R. L. Edgcumbe ... 945 440
Bed or cot invalid, G McElveen ... 945 282
Beehive, J Toth ... 945 642
Bee trap, J Nichols ... 945,467
Belt and hook uniter, R. R. Miles ... 945,[illegible]
Belt tightener, J H Hey ... 945,[illegible]
Berth guard M Schlesinger ... 945 421
Bias band folder I L. Yoel ... 945,432
Bicycle support H P Price ... 945 284
Billiard table, pool table etc., H. G Barrett ... 945,150
Billing and journal sheet, combined, J W Hartley ... 945,527
Binder loose leaf, A Benson ... 945,[illegible]
Bit chuck and bit, M Hardsocg ... 945 785
Blade mounting means, C R. Sweet ... 945,304
Boat salvage device, G Salles ... 945 141
Body brace, J U. Adams ... 945 559
Boiler casing, water tube, J Beck ... 945,[illegible]
Boiler flue scraper, H. Smith ... 945,772
Boiler water level indicator J J Dewey ... 945,[illegible]
Bolt and nut lock for connecting rails M W Smith ... 945,110
Book holder, R. R. Ashdale ... 945 257
Book rack, T R. Layton ... 945 [illegible]
Boot and shoe tree Stevens & Wakefield ... 945,[illegible]
Boot treeing machine H H Cummings ... 945 [illegible]
Boots and shoes, ventilating overmask for H M. Guenther ... 945,[illegible]
Bottle attachment R. W Becker ... 945 [illegible]
Bottle box, M F Flynn ... 945 121
Bottle, milk T L. Pamler ... 945,220
Bottle non refillable Holfroth & Remisck ... 945 [illegible]
Bottle non refillable D. A Hoyer ... 945 541
Bottle, non refillable C V Shaw ... 945,[illegible]
Bottles and the like combined holder and protector for milk, D F Jones ... 945,170
Bottles, jars, etc., closure for, L J Campbell ... 945 444
Box, R R. Fye ... 945 158
Box construction, H W Hildebrand, Jr ... 945 [illegible]
Brake shoe, J E Osmer ... 945 409
Brick driers steam distributing apparatus for E H Palloway ... 945 219
Brick machine, R. F Ollmann ... 945 [illegible]
Brooder A P Ward ... 945 [illegible]
Brush G Lange ... 945 [illegible]
Brush and means for automatically cleaning the same stripping W Phillipson et al. ... 945 591
Buffer friction, J Nichols ... 945 473
Buffing or polishing wheel F M Levett ... 945 177
Builder's jack, H W Hause ... 945 [illegible]
Cabinet, roller towel, A Allen ... 945 [illegible]
Cabinet rural carrier's, C A Dyer ... 945 014
Cable lubricator W J Slaughter ... 945 022
Cable traveler J E Magner ... 945 [illegible]
Calculating machine Querfeld & Judge ... 945 [illegible]
Can feeding device W L. Wight ... 945 [illegible]
Can packing apparatus, F J Heybach ... 945 [illegible]
Can roller mechanical M D Blakeslee ... 945,[illegible]
Can stopper attachment W. H. Van Kent ... 945 [illegible]
Can testing machine C H. & I D Mc Donald ... 945,573
Candies with sugar, apparatus for coating, Wild & Mahan ... 945 [illegible]
Car adapted for subway use A H De Paul ... 945 [illegible]
Car body underframe, M. M Schneider ... 945 142
Car construction, H H Adams ... 945 [illegible]
Car door, Warnock & Lewis ... 945 [illegible]
Car door grain W R. Driskell ... 945 [illegible]
Car fender G A Parmenter ... 945 727
Car step C. E. Hedgepath ... 945 531
Car wheel mine Parks & Davis ... 945 [illegible]
Cars, carline for box T De Vinney ... 945 [illegible]
Carbureter G M Holley ... 945,107
Carriage curtains appliance for cutting prong receiving slits in, F R. Carr ... 945,445
Carrier J C H Gerst ... 945 513
Carriers, stop for overhead A H Neller ... 945,577
Carrying apparatus A I Smith ... 945 [illegible]
Casket handle E R Sargent ... 945 [illegible]
Casting ingots, W H Connell ... 945,019
Catching and supporting device automatic J J Seinius ... 945 [illegible]
Cement kiln multitubular H L. Doherty ... 945 [illegible]
Cement, process of and apparatus for burning, H L. Doherty ... 945,207
Centering machine A A & J A Anthony ... 945 [illegible]
Centrifugal separator J W Phillips ... 945 [illegible]
Chafing dish stand G E Savage ... 945 287
Chain cutter, N D Levin ... 945,335
Cross slides, mechanism for actuating, B. M W Hanson
Chair M Anthony ... 945,149
Chair, L. O Fullam ... 945,510
Chair head rest barber's, G W Homer ... 945,518
Check pad and pencil holder, combined, C T Rawbick ... 945 [illegible]
Chuck, lathe, O J Blum ... 945,261
Churn, P E. Marugg ... 945,402
Churn J E & T G Taylor ... 945,[illegible]
Cigar tip cutter, E. Oldenbusch ... 945,541
Circuit controlling mechanism, C H Moores ... 945 473
Clay products, carrier for green T Louden ... 945,[illegible]
Cleaner See Tube cleaner
Cleaning apparatus, vacuum C R. Pollard ... 945,[illegible]
Clock, automatically plumbed J Ogawa ... 945 [illegible]
Clock ratchets forming F R. Alford ... 945 [illegible]
Clocks, motor device for electric J Grans ... 945 716
Cloth piling machine H A Shields ... 945 [illegible]
Clothes clamp, R. W Glass ... 945,451
Clothes drier, W L. Gustafson ... 945,[illegible]
Clothes line extension device, H F Mayens ... 945 [illegible]
Clothes line holder, F O Nitch ... 945,[illegible]
Clothes pin, L. L. Gobeen ... 945,[illegible]
Clutch, E C Smith, reissue ... 13,072
Clutch, H M Barber ... 945,[illegible]
Clutch, W R. Knoell ... 945,[illegible]
Clutch, H E. Marshall ... 945,[illegible]
Clutch for drill feeds, safety, R. Milne ... 945,[illegible]
Clutch, friction, A Soderling ... 945,[illegible]
Coal dust from coal breakers apparatus for exhausting W S. Carpenter ... 945,[illegible]
Coal, washing, J R. Campbell ... 945,[illegible]
Coke oven walls, preventing the destruction of, H Koppers ... 945,[illegible]
Collar, F R. Heery ... 945,164
Collar attaching device D Marinsky ... 945 [illegible]
Collar support, G Keitel reissue ... 13,070
Commode or seat, portable folding, O A. Conrard ... 945,119
Commutators or collecting rings, device for grinding, W Gerb ... 945,[illegible]
Concrete articles, manufacturing J Rogers ... 945,[illegible]
Concrete mixing machine, H C Fitzke ... 945,[illegible]
Concrete wall mold D. H Magtiel ... 945,[illegible]
Concrete wall mold D. H. Magtiel ... 945,[illegible]
Conveyor, W M Schwartz ... 945,[illegible]
Conveyor, J A. Svenson ... 945,[illegible]
Cooking utensil, A H Merrill ... 945,[illegible]
Cooking utensil handle, J H Wilson ... 945,[illegible]
Corn husker, G. F Koch ... 945,[illegible]
Corn sorter, seed, O. L. Larson ... 945,[illegible]
Cow tail holder, Fahlstrom & Richards ... 945,[illegible]
Cross slides, mechanism for actuating, B. M. W. Hanson ... 945,[illegible]
Crushing jaw, W Brinton ... 945,[illegible]
Cuff holder, E. M. Johnson ... 945,[illegible]
Cuff pin, F R. Farnham ... 945,[illegible]
Cultivator, T. D Heath ... 945,[illegible]
Cultivator lever mechanism, H. M. Ashe ... 945,[illegible]
Curbing, J. Firth ... 945,[illegible]
Curtain poles and shade rollers, bracket for supporting, A. R. Dobson ... 945,[illegible]

Curtain support, vertically adjustable, T. O. Grills ... 945,394
Cutter. See Cigar tip cutter
Cutting tool, W Smith ... 945,627
Dental chair, F Ritter ... 945,104
Dental scraper, C P Fritz ... 945,713

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc

## FOR SALE

**Inquiry No. 8918.**—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads, 8 to 40 in. Price only $40.00. Address L. F. Grammes & Sons, Allentown, Pa.

**Inquiry No. 8990.** For information regarding shoes not made of leather but similar to the same and are as durable.

## PATENTS FOR SALE

**Inquiry No. 8987.** Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power meters.

PATENT FOR SALE.—No. 908,788. Reverse Gearing—arrangement for a straight Belt instead of the annoying twisted Belt. A money maker for the right party. For sale outright. Apply L. Klein, Egg Harbor City, N. J.

**Inquiry No. 9014.**—For manufacturers of machinery, supplies, etc. to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

FOR SALE.—Patent No. 924,873 on improved screw. Can be applied to wood screws, lag screws or any article having a screw point. For particulars, address Otto Rehse, Germantown, California.

**Inquiry No. 9016.**—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

## WANTED

**Inquiry No. 9042.** Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

A WANTED, Wireless patents. Advertiser desires to purchase wireless telephone and telegraph patents for either Canada or the United States or both. Write stating full particulars and cash figure on same. Address L. V. U. Suite 605, 41 Park Row, New York City.

**Inquiry No. 9045.**—Wanted, address of rubber manufacturers in Germany.

## MISCELLANEOUS

**Inquiry No. 9029.**—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

HAIR GROWS when our Vacuum Cap is used a few minutes daily. Sent on 60 days' free trial at our expense. No drugs or electricity. Stops falling hair. Cures dandruff. Postal brings illustrated booklet. Modern Vacuum Cap Co., 566 Barclay Block, Denver, Colo.

**Inquiry No. 9036.**—Wanted, the address of the manufacturers of "Cycle Ball Bearing Suspenders."

## LISTS OF MANUFACTURERS

**Inquiry No. 9038.**—Wanted the address of the Chipman Electric Purifying Co.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

**Inquiry No. 9043.**—Wanted the address of Farney Safety Razor Co.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

**Inquiry No. 9044.**—Wanted to buy outfits necessary for agate polishing.

**Inquiry No. 9046.**—Wanted machinery used for the manufacture of all kinds of fruit boxes, baskets and crates.

**Inquiry No. 9048.** Wanted, address of manufacturers of metal table slides for extension tables.

**Inquiry No. 9049.** Wanted to buy rotary brushes suitable for a shoe shining machine.

**Inquiry No. 9052.**—Wanted to buy machinery, etc., for a beer plant that manufactures beer by means of glucose.

**Inquiry No. 9053.**—Wanted address of firms who install plants to manufacture nitrogen.

**Inquiry No. 9054.** Wanted address of manufacturers of articles made from mica.

**Inquiry No. 9055.**—Wanted address of parties interested in Log Cleaning Machines.

**Inquiry No. 9056.**—For manufacturers of window shades.

**Inquiry No. 9057.** For manufacturers of glass and china balls, used as fixtures or ornaments on lightning rod equipment also weather vanes for same purpose.

**Inquiry No. 9058.** Wanted firms who make machinery used for pulverizing soap-stone.

**Inquiry No. 9059.** For manufacturers of flexible steel chain mail.

**Inquiry No. 9060.** Wanted to buy machinery to manufacture seed corn racks.

**Inquiry No. 9061.**—Wanted the address of manufacturers of auto magnetos and permanent magnetos.

**Inquiry No. 9062.** Wanted to buy a plant for manufacturing muriatic acid.

**Inquiry No. 9063.** Wanted to buy a machine that would wrap and tie up a loaf of bread.

**Inquiry No. 9064.** For manufacturers of a cigarette making machine constructed as follows: a small metal box containing tobacco and papers, the cover contains a piece of cloth upon which is placed the paper and tobacco, the cover being closed the cigarette jumps forth.

**Inquiry No. 9065.**—Wanted to buy a second hand telephone generator.

**Inquiry No. 9066.** Wanted complete outfit for export for making rice-flakes and wheat-flakes.

**Inquiry No. 9067.**—Wanted the address of makers of the Standard Folding Typewriter.

**Inquiry No. 9068.** Wanted to buy machinery for manufacturing chewing gum, such as rolling, cutting or wrapping machinery.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates

## ADAPTABILITY OF THE GYROSCOPIC CAR TO RAILROAD SERVICE.

BRENNAN and Scherl, each working independently of the other, have recently proved that a car containing a pair of gyroscopes can be run upon a single rail and maintain its stability under varying conditions of eccentric loading, side winds, and curving track. Upon seeing a practical demonstration of this fact, and submitting the car, as the writer recently did, to various severe and successfully-endured tests, it is natural, in the first moment of enthusiasm to predict an immediate and widespread application of the system, or even the eventual abandonment of the present two-rail track and trains in favor of the monorail type. Sober second thought, however, must convince any thoughtful and practical mind that, in spite of the brilliant results of the recent demonstration, the monorail gyroscopic car, in the nature of things, can have only a more or less limited application under present-day conditions. We wish it to be distinctly understood, of course, that any criticisms which follow are in no sense hostile, and are made with a full appreciation of the skill and knowledge, both theoretical and practical, with which the car now being shown in this city has been developed

THE CAR.—Mainly because of its perfect adaptability to take the curves, whatever the degree of sharpness, with a minimum risk of derailment, the promoters of the system claim that trains of this type will be run at speeds from fifty to one hundred per cent greater than those that are possible on two-rail track Now if the new system is to compete with the old, the trains must provide at least the same capacity and comfort as the present Pullman trains It is stated that, in such cars, the weight of the gyroscopes will represent about 8 to 9 per cent of the weight of the car Structurally, the monorail car must be at least as strong, being supported, like the present type, on two points, namely, the centers of the two trucks. The trucks, however would be lightened by the reduction of the number of wheels per truck from six to say four, and as the axles would be shortened, it is probable that the weight saved in this way would be about equal to the 8 or 9 per cent represented by the weight of the gyroscope mechanism Hence, it is not likely that there would be any reduction in the weight of the car as a whole The gyroscopic mechanism, on the other hand, would be an extra cost and certainly not a very light one In the very nature of things, it must be most carefully constructed and of the very best material The motion of the car would undoubtedly be easier The lateral swaying and shocks incident to the present two-rail system would give place to a very gentle and probably imperceptible rocking motion, due to the controlling action of the gyroscopes On the curves the riding of the new type would be greatly superior, the sudden jolting of the cars against the outer rail, and the uncomfortable swaying of the passengers in the same direction when the cars are running at high speed would be entirely wanting except possibly on entering and leaving the curves Under the two-track system, the car is placed in a favorable position for entering the curve by the gradual elevation of the outside rail for a distance of from 150 to 200 feet before the curve is reached, and also by laying out the first portion of the curve as a spiral with gradually decreasing radius. If some means can be found to throw the gyroscopic car slightly toward the inside of the curve before the latter is reached, it would be advisable to incorporate it.

THE TRACK.—Although the claim which is so frequently made that there would be a simplification of the track and a lessening of its cost is justified by the facts, these advantages would not be so great as might at first be imagined. One line of rails would be dispensed with altogether, it is true; but the remaining rail would in any case have to be made far heavier and stiffer; and if, as is claimed, the speed is to be *doubled*, probably some altogether new system of track would have to be devised. In the first place the concentrated weight on each set of wheels would be exactly doubled, and, since the dynamic shocks upon the track, culverts, bridges, etc., are directly related to the momentum, and the momentum increases directly as the weight and as the square of the velocity, it follows that the dynamic stresses upon the rail, due to lack of perfect alignment, low joints, slight deviations from the true line of the curves, would for double the velocity be just eight times as great with a sixty-ton gyroscopic car as they would be with one of the ordinary type. This could be met by devising a rail with a head several inches in width, and with a depth at least twice that of the present rail. It is doubtful if the present system of cross ties and stone ballast would present sufficient solidity, and some form of permanent masonry roadbed would seem to be a necessity, at least for carrying express trains of the proposed speeds of one hundred miles an hour and over.

In the case of long-span bridges, the concentration of the weight on the center of the floor would call for increased strength in the floor beams, although in the case of deck bridges where the floor is laid upon the top chords, the trusses or plate girders might be brought somewhat closer together.

The cost of maintenance would undoubtedly be considerably reduced, since the labor entailed in keeping two rails to gage and in maintaining the proper superelevation of the outer rail on curves would be entirely eliminated. On the score of safety, provided a suitable form of track were built, the argument is entirely in favor of the gyroscopic car, and especially so on the curves.

It seems to us that if there is a future for the new system, it will be found in the construction of pioneer railways through undeveloped country, and particularly through mountainous and hilly country where the line must of necessity be very circuitous. The self-adjusting qualities of the car enable it to run around curves which would be altogether impossible for a two-track railroad The monorail track could be located around a hill or bluff, through which a two-track railroad would have to pass with heavy and expensive excavation Moreover, for this class of railroad a much lighter car would be practicable and extremely high speeds would not be demanded. This decrease in weight and speed would mean a great reduction in first cost and subsequent cost of maintenance of the system If the new type should demonstrate in service of this kind its commercial practicability, it is quite conceivable that it would be gradually applied to the more important lines of travel, and eventually to the main trunk roads.

## IMPORTANT INVESTIGATIONS REGARDING THE PROPULSION OF SHIPS.

IMPORTANT investigations, marking a new era in the study of the propulsion of ships, are about to be undertaken by the Naval Architecture Department of the Massachusetts Institute of Technology, under the direction of Prof. Cecil H. Peabody, the head of the department, and a corps of assistants and associates

Already a navigable forty-foot model is in process of construction, funds for the maintenance of this work being provided by a friend of the department. In order that the investigations may be of a practical nature, directly connected with the actual conditions of ship propulsion, the model is being patterned after the U S. S. "Manning," and will be on a one-fifth scale. The choice of the "Manning" as a type of ship for the experiments is made because Prof Peabody, under whose direction the work is to be done, was directly connected with a remarkable series of speed trials on board the ship, which were reported to the Society of Naval Architects and Marine Engineers in 1899

After the relations between the actual trials of the ship and those of the navigable model have been established, a certain basis of determination will be furnished, by which it will be possible to determine what may be expected of a full-sized ship, before the latter is built. The method which it is proposed using has been tried successfully in Great Britain to some extent, particularly for such types of vessels as the "Mauretania" and "Lusitania."

Messrs. Denny Brothers of Dumbarton, England, have a private model basin in which they have developed new types of ships, and in the case of the Japanese vessel, the "Otaki," which was built by this firm, just such a navigable model was used to determine the capacity and power of the novel combination of reciprocating engines and low-pressure turbines.

The department has been promised the co-operation of the model basin at the Washington navy yard, and preliminary tests are to be made there very soon on a [illegible] model, with a [illegible] diameter.

The problem of propulsion [illegible] Prof. Peabody, three [illegible] first, the resistance of the ship, or the force required to [illegible] the given speed; second, the power applied to [illegible] by the propeller; and third, the effectiveness of the combination of propeller and ship. From necessity and choice the propeller is placed at the stern of the ship, where it can take advantage of the wake, but where it also disturbs the natural flow of water, and consequently increases the resistance considerably above what the pull on a tow rope would be. This combined effect is exceedingly complex and obscure, and consequently has given rise to more difficulty than any other problem connected with the propulsion of ships. This is the particular problem which has been chosen for investigation by aid of the navigable model.

The model is building at the yard of Stearns & McKay at Marblehead, and the propulsion machinery has been already designed. It will consist of a gasoline-electric generating set and a motor geared for experiment work, so that conditions may be controlled over a wide range, and the measurements of power may be simple and accurate. The machinery can also be easily transferred to other hulls as the work progresses.

Upon the completion of experiments with the model built and engined to correspond with the prototype, various forms and locations of propellers will be experimented upon, including twin and triple-screw propellers, especially of the type used at present with marine turbines. The form of the hull will then be changed so far as may be without rebuilding, and the hulls of various forms of ships will be built to extend the range of the experiments.

Another important problem to be undertaken will be the steering and maneuvering, including practical work in rough and stormy seas. As this field has received but little attention in the past, much new and valuable information will be acquired.

This proposed method of investigation has the considerable advantage that a proposed design may be tried on a small and inexpensive scale simulating all the conditions of actual service, including the performance of the ship under adverse weather conditions. After satisfactory conditions have been attained by use of the model, the dimensions and conditions can be determined for the full-sized ship by the theory of mechanical similitude. The fact that this theory leads to the assignment of somewhat higher power to the ship than may be needed gives the designer a margin that may be taken advantage of, but which can be controlled by the preliminary experiments with a full-sized ship for a prototype.

The equipment will be used during the coming spring and summer by Prof Peabody and his colleagues for original research. It is confidently expected that results will be obtained which will clear up certain obscure places in the theoretical work and design of the students of the department. The training received by the experimenters in the use of the equipment will thus form a part of the laboratory equipment of the department.

---

In photographic practice it is necessary to regard as capable of affecting a photographic plate all substances which, at the maximum temperature and humidity occurring in practice, produce hydrogen peroxide with sufficient rapidity to cause a perceptible deposit of silver on a plate exposed to their influence during one week. It is well known that most oxidizing agents produce hydrogen dioxide from gaseous oxygen in the presence of moisture. Aluminium, magnesium, and zinc, even at distances of 1/10 and 1/5 inch from the plate, produce a perceptible reduction of silver in two days. Consequently these metals should not be employed in the construction of cameras or plate holders, unless they are very thoroughly lacquered. A piece of newspaper, which has lain in the sun five minutes, affects a plate within 24 hours sufficiently to cause blackening on development. The action of hydrogen dioxide in increasing quantities on photographic emulsions is represented by a curve similar to that which represents the action of light. Paper treated with potassium permanganate affords a complete protection against the action of hydrogen dioxide, as the dioxide is decomposed by the manganese oxide which is formed on the paper.

---

The perennial debate on Martian canals will probably never be settled. Before the British Astronomical Association various more or less well-known astronomers gave their views. Mr. E. A. [illegible] some pictures taken at Mount Wilson by Prof. [illegible] on which no trace of the canals appeared. Mr. E. W. Maunder, whose attitude toward Martian canals is well known, again attacked the [illegible] advancing in evidence the [illegible] agrees with Maunder that the canals [illegible] by the [illegible]

## ENGINEERING.

The North German Lloyd liner "Prinz Friedrich Wilhelm" has had an accident to its steering gear.

The N. Y. C. & H. R. R. R. announced early in 1910 that electric motor power will be used as far north as North White Plains. The delay at Wakefield now made necessary by the change from electricity to steam will be done away with.

The State Commission of Highways of New York has asked for an appropriation of $80,000 to be used by the Commission in developing experiments in economical forms of road construction which would be suitable to various weights and classes of traffic.

The Public Service Commission of the State of New York for the First District, will soon open bids for 87.77 miles of rapid transit lines. The sooner work can be begun on these subways the sooner will the terrible congestion be done away with.

A German machine manufacturer has invented a new means of power transmission by the use of steel wire. It is claimed that the system is equal in every way to leather belts, steel bands, chains, etc., and is much cheaper The wires are thin, and endless.

Sir Wilfrid Laurier, the Premier of the Dominion of Canada, has launched a bill which calls for the expenditure of $16,000,000 for a Canadian navy of 11 ships. The present indications are that it will carry 5 protected cruisers and 6 destroyers, to be built in Canada.

A special Board of Fire Control has been named by the Secretary of the Navy, to look into the question of the value of the military mast which has been installed on battleships, and report whether other masts of the same type should be placed on other vessels of the fleet

Since introducing the "Pay Within" cars in Philadelphia the number of accidents to persons has decreased 74 per cent. This is attributed to the arrangement of the closed doors and steps, making it impossible for passengers to get on or off when the cars are moving

We regret to note the death of Dr. Charles B. Dudley, consulting chemist of the Pennsylvania Railroad and president of the American Society for Testing Materials and of the International Society for Testing Materials. His contribution to the railway world was a most important one.

The total length of the new Manhattan bridge connecting the boroughs of Manhattan and Brooklyn is 6,855 feet. The total cost of the bridge, including real estate, is $15,833,600 The weight of the cables is 6,300 tons. There is provision for four trolley and four elevated tracks, one 35-foot roadway, and two 11-foot promenades.

During the remainder of the winter season vessels of the Cunard Line will steam directly to Fishguard, omitting the call at Queenstown. Since inaugurating this new port of call more than 2,000 passengers have made use of the facilities which have been provided, and have expressed themselves as being well pleased with the saving of time which is effected by cutting out the trip to Liverpool

Bids are being asked for the seats and frames of the Stoney gate valves to be embedded in the masonry of the twin locks at Pedro Miguel, and the upper twin locks and the spillway at Gatun, on the Panama Canal. Each valve is designed to operate in a well traveling on two roller train bearings with a span of ten feet from center to center, fastened to the down-stream face of the wall casing Each valve closes an opening 8 feet wide by 18 feet high.

The delay of passenger trains is often caused by a too slow method of admitting the passengers to the trains when the train platform is often crowded. Where tickets have to be examined, and passengers admitted one by one, there is always more or less delay. This can be avoided by a second series of gates. The examination of tickets is made at the first gate, which is then opened in ample time prior to the departure of the train. The passengers are then held behind the second gates until the train arrives or is ready to depart, when a number of gates can be thrown open and the passengers can at once proceed to take their trains.

The N. Y. C. R. R. Co. has asked the up-State Public Service Commission to re-open the investigation which led to an order prohibiting the use of oil-burning locomotives in the Adirondack forests during certain months of the year. The company says that it has complied strictly with the requirements of the Commission, but [illegible]

## ELECTRICAL.

The question of using low-tension metal filament lamps is receiving considerable attention abroad. Transformers are being made for this particular purpose, which are fitted with interrupters, so that they may be used on direct current lines. It has been suggested to fit each lamp with a transformer The filament of the lamp could be a closed circuit, forming the secondary of the transformer

A simple method of clarifying the air of a room has recently been suggested. It consists of an electric fan or ventilator, which is operated in a cylinder, and from a reservoir above the fan a liquid is allowed to drop on the fan blades. This is thrown out against the cylinder in a spray, through which the air drawn by the ventilator must pass This serves to collect the dust from the air The inventor of this system proposed the use of glycerine or soapsuds, but it has been found that practically as good results can be obtained by the use of water

A novel method of catching fish was described in a recent issue of the Electrical Review and Western Electrician. A trolley line running between Franklin and Columbus, Ind, skirts the White River for a considerable distance, and it has been discovered that the trolley wire is frequently tapped to furnish current for fishing by electricity An end of the wire is placed in the water, and the current stuns such fishes as come within its influence, so that they can be taken out with scoop nets The trolley company and the Indiana Fish and Game Warden are trying to break up this method of fishing

The following estimate of the value of various electrical industries in the country during 1909 has been published in the Electrical World

| | |
|---|---|
| Electrical apparatus | $275,000,000 |
| Electric railways | 475,000,000 |
| Central stations | 350,000,000 |
| Telephony | 250 000,000 |
| Telegraphy | 60,000,000 |
| Isolated plant supply | 75,000,000 |
| Miscellaneous | 50,000 000 |
| Total | $1,435,000,000 |

The value of aluminium for the field coils of railway motors has been tested in Germany It is found that the aluminium takes up less space than the copper, although a larger mass of metal is required, because no covering is required The oxide film on the aluminium provides sufficient insulation and there is no danger of destroying or weakening this insulation by charring as in the case of the cotton covering when the motor is overheated so that there is less danger of short circuits. The principal advantage, however, is in the reduced weight, as the aluminium coils weigh but half as much as the copper coils.

A writer in La Revue Electrique describes the experiments of Miroslaw Kernbaum to determine the effect of ultraviolet light on liquids. He subjected about half an ounce of water to the rays of a quartz mercury vapor lamp, and after about ten hours gas appeared to be forming. At the end of two hundred hours 260 cubic millimeters (0 016 cubic inch) of gas was produced. The gas proved to be hydrogen, while the water showed that it was charged with oxygen This experiment explains the presence of oxygenated water in snow and rain It is proposed to use this method for sterilizing liquids, as oxygenated water is an excellent germicide.

Now, that aerial navigation is coming to be considered seriously new problems are arising, such as the question of navigation on starless nights or over fog bound land, when the aeronaut will be unable to find his bearings. It has been proposed by a German inventor that a network of wireless stations be established over the land, each automatically sending out a predetermined signal at regular intervals, which would be received by the air craft, and enable the aeronaut to determine his course The airships would not be required to carry transmitting apparatus, as a small receiving apparatus would suffice to enable them to avail themselves of this proposed system, and the weight of the receiving device could easily be kept down to a few pounds.

A new method of determining the sag of overhead wires has been suggested by a writer in the Elektrotechnische Zeitschrift. The pendulum principle is employed. The sagging wire is set to swinging, and the number of oscillations per minute is noted (the complete motion back and forth being considered, according to European practice, as made up of two oscillations). Letting $N$ stand for the number of oscillations, the sag in centimeters is determined by dividing 447,300 by $N^2$ To find the sag in inches, divide 176,103 by $N^2$. Of course, this formula would apply to any distance between poles and any weight or quality of wire, because like the pendulum the period of the oscillation is determined only by the vertical distance between the center of gravity and the ends or pivots of the swinging wire.

## SCIENCE.

Prof. E. E. Barnard of Yerkes Observatory has succeeded in obtaining a photograph of Halley's comet which shows a faint slender straight tail So far as is known, this is the first photograph to show the tail of the present returning comet.

A new estimate of the earth's age has recently been given by Prof William Morris Davis of Harvard For the usually accepted one hundred million years he estimates sixty million, based on an examination of the cliffs in Arizona and Utah where the time taken to deposit the strata can be easily computed

One objection to glass roofs is that if they are not very steeply inclined, the water of condensation collects on their under surface, and instead of running down along the separating ribs of the panes or plates, and being led off, drips upon persons or objects below, which is inconvenient and may be very expensive Even where the panes or strips are short, the path to the trough is too long The increase in length and width of the plates now used makes this difficulty of more and more importance each year One way of getting around it is, however, similar to that employed in forests and parks to prevent washing away of the hillside paths, namely, making inclined grooves toward the sides, only in this case the grooves are of horseshoe shape, and form a series of parallel corrugations which carry the drops to the ribs which separate the plate, they then follow these without much difficulty down the slant to the trough below This system may be employed either with glass sheets in which wire is embedded or with plain plates.

We notice in a recent number of the Medical Record a letter from Dr Robert I Watkins, New York city, in which he claims the credit of having applied the moving picture to the microscope. He states that as far back as 1897 he demonstrated the machine to a private audience, among whom was the Editor of the SCIENTIFIC AMERICAN The machine, known as the "micromotoscope," was described in our issue of July 31st, 1897 Later, microscopic moving pictures were exhibited at the Grand Central Palace during the Trained Nurses' and Pure Food Exhibition, the pictures thrown on the screen exhibiting the circulation of the blood in the web of a frog's foot, rotifers in stagnant water, an amoeboid leucocyte, typhoid fever germs, and many others. Since that time Dr Watkins has greatly improved his rough apparatus, and gave a demonstration on June 17th last at Chicago before an audience of five hundred physicians of the National Eclectic Association We may venture to point out that Dr Comandon employs not the ordinary mircroscope, but the ultra microscope

The third paper dealing with the results of the Smithsonian African expedition under Col Theodore Roosevelt has just been issued by the Smithsonian Institution It describes a new species of *Octocyon* to which the specific name of *virgatus* is given This new animal is a small carnivorous mammal closely resembling a fox It is generally buff in color, and it has been found by Mr Gerrit Miller of the museum staff to differ slightly from *Octocyon megalotis*, which occurs farther south, especially in color and in the characteristics of its teeth and skull The octocyon is peculiar to Africa, and is not represented in the United States, but resembles in color the swift or kit fox of the western plains The skull of this new form closely resembles that of the gray fox of our native fauna. This announcement is of special interest for the reason that comparatively few new forms were expected from this region in Africa as the territory up to this time explored by the Smithsonian African expedition has been pretty thoroughly examined by British naturalists.

The water bottle for getting water for analysis from selected depths in the ocean is a cylinder of brass, German silver, or other metal which resists the corrosion of sea water, generally about two inches in diameter and twelve or fourteen inches long, with upward-opening valves at the top and bottom, connected together on a central stem Lugs are cast on the side of the cylinder for conveniently securing it at any point along the length of the line by which it is to be lowered into the sea During the lowering of the line the valves of the bottle are kept unseated by the passage of the water through the cylinder during its descent, but, when the motion is reversed, the valves seat themselves and are locked by the descent of a small propeller in the framework above the upper valve, which rides idly on a sleeve during the lowering of the bottle, but descends along a screw thread to press the valves upon their seats when the line commences to be hauled up. A specimen of the water at the depth to which the water bottle has descended is thus brought to the surface confined within the bottle, and a series of specimens from different depths may be obtained at one haul by securing a series of water bottles at the required intervals along the sounding line.

# THE SCHERL GYROSCOPIC MONORAIL CAR

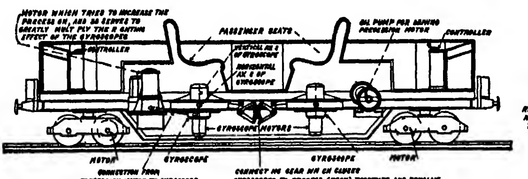
## THE PRINCIPLE OF ITS OPERATION

Within the past few months Mr Brennan has exhibited at London a car whi h runs upon a single rail and is prevented from fall ng over to either side by the resistan c of two gyros o| es carr ed on the car At about the same ime Mr S herl a German capital ist exhibited in Berlin a similar ar B tl cars were of sufficient size to a commoda e passengers both car

The gyroscopic car inclines automatically to the inside of a curve

ried their loads successfully and in ea h ase the gyroscopes maintained the car in a state of equilibri im —and they did this even when all tl e load was placed to one side of the car or when the car was running around a urve

Apparently the inventors worked quite independently of each other and it is a remarkable fact that in the essential elements for the control of the gyroscopic mechanism they should have produced machines so broadly identical The G rman car whic l is now be ing exhibited in this city represents the joint labors of Mr I a l Froeli h the inventor who worked out



Longitudinal secti n thr ugh Scherl gyrostatic car

the theory and data for the design Mr Emil Falcke who designed and constructed the car and Mr Scherl the owner of the patents

THE GYROS OPE.—The simple gyroscope consists of a flywheel so mounted upon a system of bearings that its axis may be tilted in any direction The pe uliar and most interesting behavior of the gyroscope is due to tle fact that wh n a flywheel so mounted is rotat ing in a given plane it resists any effort to change its plane of rotation by til ing the axis on which it is turning Th tendency of the flywheel to maintain its plane of rota ion and i s resistance to any force tend ing to til it out of that plane is proport i on a l to i t s momentum and since momen tum in reases di rectly as the weight and as the square of the velocity it is cus tomary to use as small a weight and as high a velocity as possible Hence the fly wheels used in the Scherl car weigh only 125 pounds each but they rotate at the enormous speed of 8000 revolu

If the table (representing platform of car) be tilted transversely the gyroscopic flywheel will tilt fore or aft according to the direction of its rotation, and there will be developed a strong resistance to the movement of the table. This fore-and-aft movement is called the precession.

View showing gyroscopic movements.

THE SCHERL GYROSCOPIC MONORAIL CAR.

tions per minute We are all familiar with the gyroscope of the toy shops or the lecture room—the first mounted rotatably in one the second in two encom passing rings with the axes of the rings at right angles to each other and the flywheel axis in each case capable of universal angular motion In the accompanying engraving we show a gyroscope mounted as in the Scherl car The flywheel is car ried on a vertical axis which is mounted in a gimbal ring This ring swings on a hori zontal axis in bearings carried on two ver tical posts mounted on a board which, for the present purpose we will consider to represent the deck of the car If we change the plane of rotation of the flywheel by pressing down on one side and tilt ing it over toward *B* two things will happen The board will resist the downward pressure on that side and tend to rise and the flywheel will be suddenly tilted over as shown in the direction *D* in a plane at right angles to the plane in which we have depressed the board

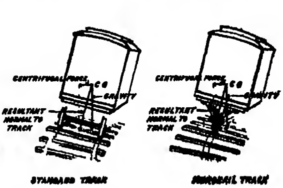
This tilting of the axis is known as its precession If now we en deavor to increase the precession by pressing down upon the already tilted axis the latter will resist v ry strongly and there will be developed at the same time a large additional resistance to our depression of the side *B* of the board It is in this advancement of the pre ssion as Brennan alls it though the pre cession be ause of he vigorous resistance of the fly wheel axis is not actually advanced) that the secret of the successful gyroscopic car lies as will be evident from the following des ription of the onstruction and operation of the Scherl car

Referring to the engraving showing a longitudinal section it will be seen that the car which is 4 feet wide by 18 feet long is carried on two 2 wheeled swivelli g trucks | laced centrally below the longitudi nal axis of the car It is driven by two ¾ horse power motors one on ea h truck At each end is a controller and a box containing various operating switches In the center are two seats accommodating four passen gers

Mounted in the car frame underneath the seats are two gyroscopes one of which rotates lockwise the other anti-clockwise The flywheels rotate normally in a horizontal plane on vertical axes On the lower end of each axis is mounted an electric motor The axes are jo irnaled in strong steel airtight casings which completely inclose both motors and flywheels and the gyroscopes run in a perfect vacuum—this to avoid the skin friction of the air which would retard the speed. The casings are mounted on transverse axes, jour naled in the frame of the car and they are therefore free to rock in a fore-and-aft direction The clearance between the motor and the casing is so small that the heat of the motors can jump the insulating gap and radiate away freely and "heating up" is thereby avoided The speed of rotation of the 125-pound fly wheels as we have stated above, is 8000 per minute.

With three men on one side, car tilts to opposite side, restoring equilibrium

The rocking of the gyroscopes is in opposite directions —if the car is tilted to one side they rock toward each other and *vice versa* and to insure simultaneous and equal movement they are connected together by bell crank levers and two toothed quadrants as shown in the drawing In front of the gyroscopes is an electri ally driven oil pump for generating hydraulic pres sure to drive a precession motor which is carried at the rear of the gyroscopes The precession motor con sists of a cylinder and piston controlled by suitable valves These valves are themselves operated by the rocking movements of the gyroscopes and the move



Old and new method of rounding curves.

ments of the piston are caused through suitable me chanical connections to exert a tilting pull or push, as the case may be against the gyroscope

The functioning of this most ingenious mechanism is as follows When the car tips or tends to tip to one side there is an immediate resistance tending to right the car accompanied by a precession (tilting) of the gyroscopes This natural precession actuates the valves of the precession motor which in turn tilts or attempts to tilt the gyroscope still further on its traverse axis and so increase the precession The gyroscope however strongly resists and there is a resulting reaction transversely to the car tending to right the latter so that the righting effect due to the "natural" precession is greatly augmented by the "mechanical precession" attempted by the motor. [illegible]

sum of all the forces passing through the single rail on which the car runs.

One of our illustrations shows the Scherl car with three people standing on the side step, and it will be noticed that instead of the car inclining toward the loaded side, it actually inclines away from it. This, however, is in agreement with the facts observed in our consideration of the gyroscope, where the pressure on one side was immediately resisted by a counteracting force, causing that side of the gyroscope to rise. In the unloaded condition of the car the gyroscopes were holding it in a state of equilibrium with the center of gravity vertical above the rail. When the three people stepped upon the car the center of gravity moved over correspondingly until it was several inches outside of the rail causing the car to lean to that side. Immediately the gyroscopes began to pull the car over to the left until the center of gravity of the car and the three people was directly above the rail and equilibrium was restored. So sensitive and intelligent, if we may use the term, is the relationship between the gyroscope and its precession motor that they begin to act immediately upon the disturbance of equilibrium, they exert just the right amount of corrective force; and they become quiescent the moment equilibrium is restored.

Another of our photographic views shows the striking phenomenon of a car running around a curve upon a single rail and inclining inwardly to the proper degree to maintain its equilibrium. To practical railroad men this is certainly the most attractive feature of the invention, for it would mean the elimination of all the difficult contradictory and expensive problems connected with the super-elevation of the outside rail on the present two-rail tracks. It is a fact that the car is so intelligent (we cannot help using the term) that whether the curve be easy or sharp and whether the car rounds it at ten or seventy-five miles an hour it will lean inwardly with mathematical certainty to the exact amount required by its speed and the sharpness of the curve.

In the standard system of track the component of centrifugal force tending to hurl the car over to the outside of the curve or cause it to jump the track is equalized by elevating the outside rail until the resultant of gravity and centrifugal force falls normally to the track. This condition can only hold true on any given curve for a certain speed. Below that speed a train will grind on the lower rail; above it will crowd against the outer rail. Not so with the gyroscopic car. As soon as it enters a curve the pull of centrifugal force is resisted and the gyroscopes draw the car over to the inside of the rail until the resultant of all the forces acting upon it passes through the rail.

The gyroscopic car as above described is one of the most brilliant inventions of this or any age. But is it practical and will it pay? A discussion of this question will be found in our editorial columns.

## THE DEATH OF LEON DELAGRANGE

After making a wonderful new record of 124 miles in 2 hours and 32 minutes on December 30th with a Bleriot monoplane, Leon Delagrange, who with Henry Farman was the first aviator to make flights with the crude Voisin biplane in France in the spring of 1907, met his death by a fall with the same monoplane on January 4th while flying at Bordeaux. Our photograph shows M. Bleriot with Delagrange standing at his left and Le Blanc, another daring pilot of the Bleriot machine, at his right. Behind the three men stands the machine which is like that Bleriot used in crossing the Channel and which Delagrange used on the day of the accident. A rather strong wind was blowing and according to cable reports when the machine headed into the wind the right wing suddenly broke and the monoplane fell to the ground. This is the first accident which has occurred owing to the collapse of an aeroplane when in the air. We understand, however, that some time ago a similar accident happened to Latham, but without disastrous results. One wing of his Antoinette monoplane broke off and stood almost at right angles to the other wing, yet by leaning to one side and warping the remaining wing, Latham was able to guide his machine down in circles and bring it safely to the ground. After repairing the wing he attached it in such a

Le Blanc Bleriot Delagrange

BLERIOT AND HIS TWO PILOTS IN FRONT OF HIS NO. 11 TYPE MONOPLANE.

way that when he was up in the air he could pull a cord and cause the wing to break off as before. He did this and came down a second time with the wing broken, simply to demonstrate that a broken wing did not necessarily mean disaster. In the Antoinette machine the wings are secured separately to a mast so that the breaking of one does not affect the other. In the Bleriot monoplane the wings are connected together over a tripod, the result being that if one breaks the other collapses and the machine is sure to be dashed to the ground.

The death of Delagrange will put a damper upon the ardor of some enthusiasts for a time, but it was due to one of those unfortunate accidents which are always liable to occur in the development of a new art. His name will go down to history as one of the martyrs of aerial navigation. He is the fourth aviator to be killed within the past four months, the others being Lefebvre (who plunged to earth in his Wright machine), Capt. Ferber (who struck the ground when making a turn in his Voisin) and the Spanish tailor Fernandez (whose small biplane resembling the Curtiss broke while he was making one of his first flights on December 6th last). All four fatal accidents occurred in France.

## A NEW ENGLISH TRIPLANE

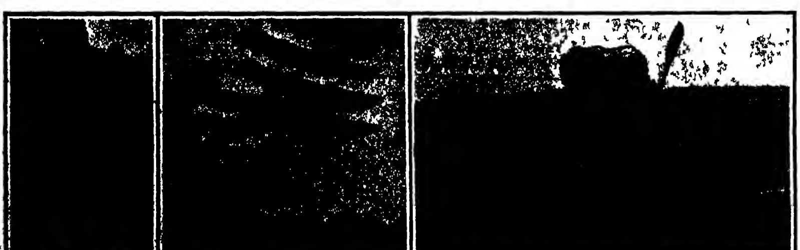
One of our illustrations shows the new triplane of Mr. A. V. Roe. Mr. Roe is one of the most persistent English experimenters. He has been working a long time and has finally developed a successful machine. His triplane is really a Langley type machine in triplicate since it has three superposed surfaces forming a tail and attached like the forward planes to a triangular body. The motor is mounted in the body at the front end of the machine and drives a three-bladed propeller mounted upon its crankshaft. The aviator sits in the body about half way between the main planes and the following planes or tail. The machine is mounted upon two wheels at the front and a skid at the rear. It is 23 feet long and the planes have a spread of 20 feet and 320 square feet of supporting surface. They are set at an angle of five degrees. The forward planes are 20 feet by 3 feet 7 inches while the rear planes are 10 feet by 3 feet 7 inches in size. The total weight of the machine originally with a 10 horse-power Jap motor was but 400 pounds. A larger motor of 20 horse-power has been fitted. The weight has been considerably increased. The body is made of deal wood. It is covered with cotton oil paper backed with muslin. The machine is steered up and down by changing the inclination of the main planes which are pivoted so they can be turned. There is a vertical rudder at the rear. The machine is steered by working this rudder and at the same time twisting the rear edges of the main planes.

Mr. Roe has done most of his experimenting at Wembley Park and recently the grounds have been enlarged there so as to give him more room. He has made a considerable number of short flights in a straight line and his machine is remarkable for its low power, light weight and small spread.

## AVIATORS' COSTUMES AND A MACHINE FOR TEACHING BEGINNERS.

Two of the photographs reproduced on this page give a very good idea of the costumes worn by French aviators and of the dress soon to be adopted in France by the lady operators or aviatresses. The costumes used by the men consist of overalls and jumper and a tight-fitting skull cap completely covering the head. The costume being used by the lady operators consists of a loose blouse and long bloomers extending to the tops of the shoes. A skull cap similar to that used by the men is also worn. At the present time but two ladies have made flights by themselves in aeroplanes in France. These are the Baroness de la Roche, who operates a Voisin biplane and who recently met with an accident by running into a tree, and Mlle. Marvingt, who is the first woman in the world to have flown a monoplane. She has made several successful flights with a Hanriot machine. A number of other ladies are learning, however, and several aviation clubs have been formed for women. One of the most recently organized of these was formed at Los Angeles, Cal.

Another interesting picture at the bottom of this page shows a novel training machine for accustoming aviators to a monoplane of the Santos Dumont type. This machine consists of a substantial triangular body mounted upon three wheels and terminating in a tail having movable vertical and horizontal surfaces by which the machine is steered to right and left when running along on the ground or by which the tail is made to rise a short distance in the air. The two bottom members of the triangular frame are extended forward and meet above a small wheel five or six feet ahead of the main wheels so that if the machine tips forward when the tail rises the front wheel keeps it from tipping too far. A four-cylinder water-cooled motor of 40 horse-power is mounted upon a U-shaped frame and carries a propeller in front on its crankshaft. The would-be aviator sits in a small seat below the motor with the control levers conveniently at hand. The machine is fitted with large wire wheels fitted with large diameter pneumatic tires. With this machine a beginner can travel at very fast speed over the ground and accustom himself to the steering sideways and up and down of a monoplane. The machine should serve a useful purpose in training aviators who intend to fly this type of aeroplane.



French aviation costume. Roe's triplane in flight. Machine for familiarizing beginners with an aeroplane.

A NEW ENGLISH TRIPLANE AND A FRENCH MACHINE FOR TEACHING NEW AVIATORS.

## A POWER-DRIVEN SAW.

The continuously running flexible saw is by no means a novelty to our readers.* Its leading principles are embodied in the band saws now in common use. Although effective for sawing lumber band saws are incapable of cross-cut sawing on large trees in the forest because the band necessarily runs in two planes For the purpose of overcoming this objection Mr R L Muir has perfected a new style of endless cross-cut saw which is flexible in a single plane of motion and which is carried in a frame which with the idle side of the saw follows the saw-cut through the log the frame being sufficiently stiff and rigid to keep the saw in perfect line

The frame in question 1 is made of thin steel with grooved edges Projecting brackets 2 and 5 are bolted to the ends In the brackets guide wheels 3 and 4 with grooved peripheries are journaled The bracket 5 has a handle by which the operator controls the saw An endless chain composed of saw links 6 is mounted on the guide wheels and runs on the straight edges of the frame The guide wheels on the frame serve to keep the chain straight during operation This frame and the toothed chain constitute an endless saw which runs continuously and which makes a single saw cut in the plane of its motion The saw moreover is adapted to all kinds and styles of sawing for which either circular saws band saws or mechanically driven reciprocating saws can be used and for which hand saws are ordinarily employed the two handled cross cut saw being a familiar example

The chain saw is driven by a gasoline or electric motor the inner guide wheel being geared up with the motor shaft as indicated in our front page illustration The motor is carried on a skid which skid is moved along on ways whenever a new cut is to be made

Mr Muir has carried on extensive trials with the saw in the vast redwood belts of Mendocino and Humboldt Counties in California with remarkable success The most important advantage of his construction is that of the speed One of his large saws it is asserted will cut through a tree having a diameter of some five to seven feet in less than ten minutes By the old and slow hand process this same work would consume an hour and a half with two men wielding the saw One of the machine saws will accomplish as much as from 25 to 30 expert sawyers a wonderful saving in time and expense when it is considered that only two or three men are needed to operate a machine The saws can be run horizontally vertically or on an incline Trees can be sawed within a few inches of the ground—a great saving thus being effected in stump waste In felling trees of immense size by the slow chopping methods hundreds of feet of valuable timber are lost by chippage because it is often necessary to cut up so high as eight feet above the level of the stump The mechanical saw described avoids much of this waste

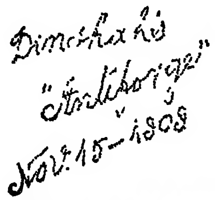
## AN ELECTRIC PERFORATING PEN

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

Though various efforts have been made from time to time to evolve an electrical system of securing an indelible writing record which is complete proof against both forgery and fraud such devices have proved commercially impracticable A Parsee inventor however Dr Dinshah P Ghadiali has evolved a simple apparatus which is very efficient It is called the antiforge pen which as its name implies is to render forgery impossible The writing is made up of a series of perforations burned in the paper The apparatus comprises a small box with a sloping lid measuring about 20 inches long by some 16 inches wide The whole of the electrical equipment is carried within the box or desk the lid of which is glazed and carries at its upper end a sheet of aluminium The pen itself is of the ordinary stylographic type

The requisite current is drawn from a small 7 ampere storage battery as shown at *A* in one of the illustrations The battery is connected up in the usual manner to an induction coil *B* to which is fitted a small high-speed trembler capable of adjustment by a thumb-screw on the outside of the desk Between the secondary terminals of the coil a small cylindrical condenser *C* is placed in order to increase the intensity and fatness of the spark

In an electric system of writing care must be taken to prevent the inside of such letters as o d e and so forth from dropping out which would result if the outline were continuous This possibility is obviated by means of the trembler coil which makes the current rapidly intermittent At the same time however such rapidly succeeding waves of electrical energy rising up to 10 000 volts instantly followed by a drop to zero, impose a severe strain upon the induction coil, and will in time seriously affect it. To guard against such a result the inventor has introduced a novel device which may be best described as a safety valve to the coil This is a highly exhausted vacuum tube, *D* which is also placed between the secondary terminals and which is in parallel with the pen *E* This etheric buffer" or vacuum tube acts as a ballast load upon the coil, and any resistance which may be offered to the passage of the electric current through the pen is taken up thereby causing it to glow brilliantly At the same time it also acts as a galvanometer as before writing the operator simply presses the pen point against the desk, and the resultant glow in the vacuum tube indicates that the apparatus is working efficiently

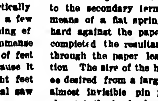


Specimen of writing with the electric pen.

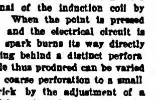
The pen is about the same length as the ordinary fountain pen and its barrel contains a mercury break The connection with the coil is effected by a short length of flexible wire carried on a spring barrel By means of the mercury break contained in the barrel the primary circuit is never closed until the pen is held in the normal writing position Even then the current cannot flow to the point of the pen because the cone shaped extremity carrying the metallic writing point is separated from the barrel connection by means of a spring piston It is only when the pen point is pressed upon the paper wherein the metallic extremity is pushed inward against the mercury that the current can flow to the pen point

To use the pen the sheet of paper is laid upon the aluminium pad which on its under side is connected to the secondary terminal of the induction coil by means of a flat spring When the point is pressed hard against the paper and the electrical circuit is completed the resultant spark burns its way directly through the paper leaving behind a distinct perforation The size of the hole thus produced can be varied as desired from a large coarse perforation to a small almost invisible pin prick by the adjustment of a rheostat the knob of which projects from the left hand side of the desk

With the metallic point only the perforated outline of the writing is produced but it may be desired to secure a legible distinct surface inscription as well In this case the metallic point is replaced by a small length of graphite—that taken from an ordinary lead pencil acts excellently Then in writing one secures a visible surface record and when held up to the light a perforated record may also be seen In order to obviate the necessity of holding the paper to the light to see if the perforating is being efficiently effected, there is a small metallic filament lamp and reflector fitted inside the desk and by pushing a button on the left hand side the writer can ascertain the results by examining the writing in the light transmitted through the glass desk lid



The "desk" open, showing the coil and accessories.



The inventor using the perforating pen.

AN ELECTRIC PERFORATING PEN

By this method of writing it is impossible to produce two signatures exactly alike, even if written by the same person. The reason is that the electric spark in its path through the paper follows the line of least resistance, and the perforation is consequently irregular instead of occurring at regular intervals. The best prepared paper contains infinitesimal obstructions, and these the electric spark avoids. The result is that the operator cannot even produce an exact facsimile of his own handwriting, though each is absolutely correct. This peculiarity is a distinct advantage when it is required to sign a number of sheets of a document, a bond and its duplicate, a will and its copy, for instead of signing each sheet separately the papers are simply superimposed and the top sheet written upon The current will burn its way through the whole mass of papers so that the signature is written simultaneously on each and in perfect duplication. Consequently it is absolutely impossible fraudulently to withdraw one sheet and insert another with a signature, for it is only a matter of counting the number of dots or perforation marks in the signature on each sheet, and that which differs from the rest is obviously spurious As many as eight sheets can be perforated by the pen at a time

## The Payroll of the Navy.

To provide for the welfare and comfort of the officers and enlisted men of the navy during the fiscal year of 1911 it is going to cost Uncle Sam just $5 767,477 Of this amount over $5 000 000 will be spent to buy food for the 46 499 enlisted men. The Navy Department figures that it costs the government $108 a year to feed each man, or just $9 a month The payroll of the enlisted men in the navy during 1911 will aggregate nearly $18 000,000 This sum will take care of 41 723 in the general service 454 men in the insular force and 1 156 prisoners under sentence by court martial

About one-fourth of the men serving in the navy today have re-enlisted Of the 43 333 allowed by law 11 681 men are estimated as under re-enlistment and entitled to participate in the allowances for re-enlistment and continuous service These figures do not take into consideration the 3 000 or more apprentices. Based on the men in the service in June last the average pay of the enlisted men was $35 73 a month.

The perquisites allowed officers in the navy will aggregate nearly three-quarters of a million dollars in 1911 Of this amount $144 449 will be spent in providing heat and light The heaviest cost in the allowance granted the naval officers in addition to their pay is in the matter of quarters for those who can not be accommodated in buildings or houses maintained by the government The commutation of quarters will aggregate $435 780 while the commutation of rations figured at 30 cents a day will reach a total of $165 456

## An Electric Plant Operated by an Air Turbine.

Near Hamburg Germany is a small electric establishment concerning which the following interesting details have been published The installation comprises 400 incandescent lamps and five electric motors, which drive a threshing machine a hay cutter a cream separator and two pumps. The total capacity is 40 kilowatts. The Hercules turbine has a wheel 40 feet in diameter mounted on top of a steel tower about 100 feet high The apparatus begins to work as soon as the wind attains a velocity of 10 or 12 feet per second In this region a wind of this force can be counted on for 10 hours a day on the average With a wind of 26 feet per second the power developed is 30 horse-power or 22 kilowatts. The installation also includes storage batteries and a gasoline motor for use in calms. The turbine operates so satisfactorily that it was unnecessary to use the gasoline motor during a period of 90 consecutive days. The storage battery of 60 elements, has a total capacity of 495 ampere hours, and furnishes a current of 165 amperes for three hours. The first cost of the establishment, including the gasoline motor, was about $8,000, while the plant which it replaced and which was operated entirely by a gasoline motor, cost only $5,000 On the other hand, the annual cost of operation of the electric plant is only $1 100, while that of the old plant was $1,700

The work of extending the electric zone of the New York Central Railroad as far as North White Plains is proceeding quite rapidly, and it is expected that by the first day of next year it will be in full operation. The temporary terminus at Wakefield, where steam and electric locomotives are interchanged, will then be abandoned. A new substation is being erected at Tuckahoe and another one at White Plains. Both will be equipped with three 1,000-kilowatt rotary converters and nine single-phase transformers of 375 kilowatts capacity.

## LOCALIZING GASOLINE EXPLOSION

To the Editor of the SCIENTIFIC AMERICAN

The recent explosion of a gasoline tank on an automobile and also one in this vicinity of an autoboat both attended with fatalities has suggested to my mind a facile means of rendering these explosions harmless. A number of years ago I was reading a description of a powder factory and one of the means used to minimize danger was in the construction of magazines. In order to localize the effect of explosions, the warehouses and some of the factories were built on the edge of a river The five sides not abutting on the river were made extraordinarily strong while the side fronting and opening on the river was made correspondingly weak. As forces seek the avenue of least resistance the houses so constructed were analogous to a gun barrel the explosion was localized and its force expended more or less harmlessly over the face of the stream How easy then to see a gasoline explosion rendered innocuous to the occupants of a motor vehicle Simply by making the reservoir analogous to a gun barrel Constructing the back and barrel of the gasoline reservoir in cylindrical form of boiler plate say ⅛ inch thick the rear end pointing in the clear, toward the rear of the vehicle The explosion then is similar to that of a rifle or shotgun and is directed harmlessly away from the occupants The rear end may have valve seat bearing and be clamped in with a spring to resist ordinary wear vibration and pressure but yielding harmlessly to explosive force Thus an explosion of gasoline in the reservoir need cost no more than a recharge of that volatile spirit, and the labor of reclamping the rear end G OC MCMANUS

## CONTINUOUS BISECTION OF A MILE

To the Editor of the SCIENTIFIC AMERICAN

We all know that the middle and western portions of this country are laid out in mile-square sections which can be continuously bisected to form homesteads of 160 acres and then smaller lots whose size and location can be briefly and accurately described

The last whole number that we reach by subdivision in this manner in feet is 165 and this would form the sides of a square whose area would be 100 square rods.

Continuing the bisection of this 165 feet through inches and fractions thereof we presently reach the length of 30 9375 inches which approximates to the U S military step by 0 0625 inch an amount inappreciable in actual measurement by pacing Now this length of pace is that of the standard axe helve measured from the inside of the bit to the end of the handle. It is the length of the average human arm and reminds one of the South American vara of 33 or 34 inches which also probably had its origin in the length of a pace. Being squared it will divide evenly of course into any of the above-mentioned divisions of land and the periphery of such square is ¼ inch less than that of the standard wagon bed of the middle west, which is coming more into use as a measure of capacity If we make a cube of this dimension the contents of four such cubes would project above the sides of such wagon bed 1/10 inch an amount which would require careful measurement to detect One such cube, filled with water would hold close to one cubic foot of water more than the one-half ton of 1,000 pounds, and would divide into the cubic meter [illegible] times.

But a remarkably close approximation to our standard measures of capacity is found in further twice bisecting this length of 30 9375 inches. We find thus a length of 7.73 + inches, which, cubed as before approximates the capacity of two of our standard liquid gallons within two-thirds of a cubic inch.

These approximations, useful to the military man [illegible] the farmer for rough and limited [illegible] under [illegible] statutory [illegible] in the metric [illegible] length, area, [illegible] [illegible]

"quarter" hour instead of so many dimes or so many minutes, "half" ten or "half" pound instead of so many pounds or ounces. Observe too that it (continuous bisection) is the method we use in deriving all of our lower measures of volume

## SIGHTING A RIFLE.

To the Editor of the SCIENTIFIC AMERICAN

Every marksman is familiar with the effect of raising or lowering the rear sight on his rifle Perhaps not so commonly understood is the effect of raising or lowering both front and rear sights simultaneously

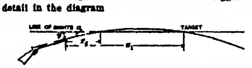
On point-blank range the target front and rear sights lie in the same straight line when the gun is correctly pointed The trajectory of the bullet is a curve intersecting this straight line in two points one of which is the center of the target It therefore follows that if a rifle is correctly sighted for one range there is another range for which it is equally correct and it is the purpose of this article to show how these two points may be located at will by correctly arranging the elevation of both front and rear sights

The most accurate shooting is done with 0 22-caliber rifles at ranges of from 25 to 50 yards and when once the sights are correctly set for one range no marksman likes to change them It may therefore be of interest to know how they may be set for correct work at two ranges which may be a considerable distance apart

The path of a projectile *in vacuo* is a parabola and since air resistance may be neglected for very short ranges and low velocities the parabola equation will be correct enough for our purposes The equation is usually stated thus

$$y = x \tan a - \frac{g x^2}{2 v^2 \cos a}$$

$y$ is the distance from the line of sights to the center of the gun barrel $x$ the range $g$ the acceleration of gravitation and $a$ the angle between the line of sights and the center line of the gun barrel The relation of those quantities is all shown in exaggerated detail in the diagram



Since the angle $a$ will be quite small for short ranges we may replace $\cos a$ with unity which is practically its equivalent thus simplifying the equation This gives us

$$y = x \tan a - 16 1 \frac{x^2}{v^2}$$

Taking data from a Winchester 0 22 rifle equipped with globe sights and sighted for 75 feet we have $y$ = 9/16 inch = 0 0468 feet $v$ = 1 000 feet per second

$$\text{Thus}\quad 0\,0468 = x \tan a - \frac{16\,1\, x^2}{1\,000^2}$$

Reducing to the form $x^2 + \frac{b}{a}x + \frac{c}{a} = 0$ in which the product of the roots equals the third term we have

$$x^2 - \left(\frac{1\,000^2}{16\,1}\tan a\right)x + \frac{1\,000^2}{16\,1}\,0\,0468 = 0 \qquad (1)$$

$$\text{Calling the roots } x \text{ and } x_1,\ x\ x_1 = \frac{1\,000^2}{16\,1}\,0\,0468$$

$$x = 75 \text{ feet}\quad 75\,x_1 = \frac{1\,000^2}{16\,1}\,0\,0468\quad x_1 = 39 \text{ feet}$$

Thus when one range is 75 feet the other is 39 feet which is too close to be of any use We see also that the 75-foot range is on the falling side of the curve so that a little greater distance will land the bullet below the mark.

To bring $x_1$ on the farther side of $x$, it is evidently necessary that $y$ must be increased or in other words both the front and rear sights of the rifle must be elevated

We will now find the value of $y$ so that the gun will shoot correctly at both 75 and 150 feet As before

$$x^2 - \left(\frac{1000^2}{16\,1}\tan a\right)x + \frac{1000^2}{16\,1}\,y = 0 \qquad (2)$$

Taking the product of the roots equal to the third

$$\text{term}\quad 75\ 150 = \frac{1\,000^2}{16\,1}\,y\quad y = 0\,181 \text{ feet} = 2\,17 \text{ inches}$$

Thus by setting the front sight 2.17 inches above the center of the bore and elevating the rear sight till the gun shoots correctly at 75 feet it will be found also correct at 150 feet. Moreover it may be shown that at no range between 75 and 150 feet will the error be more than 2.4 inches The angle of elevation of the sights may also be determined from the equation but it is much easier to get this angle right by means of trial shots, as it is very small and difficult to measure Its determination is as follows In equation (2) the sum of the roots equals the coefficient of $x$ with its sign changed Thus

$$75 + 150 = 225 = \frac{1\,000}{16\,1}\tan a$$

$\tan a = 0\,00362$ $a$ = 12 min. 27 sec

Of course all the above results are based on the assumption that the velocity is 1 000 feet per second which is about correct for a 0 2 short cartridge Below is given a table in which the values of $y$ are worked out for other velocities and ranges

Air resistance which causes the projectile to depart from a parabolic path will have the general effect of causing the tabular values of $y$ to be too low but this effect is not very noticeable for the short ranges and low velocities which are common in 0 22 caliber marksmanship

The results are not intended to apply to high power rifles and long ranges although the departure of the projectile from a parabolic path does not alter the fact that any rifle may be correctly sighted for any two ranges within its limit

| Velocity in Feet per Second | Height in inches of front sight above center of gun barrel for different combinations of ranges in feet | | | | | | |
|---|---|---|---|---|---|---|---|

Warren O WILLIAM C WOODLAND

## The Light of the Firefly

After referring to the original work of Profs Langley and Berry and describing accurately their methods of investigation Dr H E Ives and W W Coblentz draw from their own investigations the following very interesting conclusion as to the relative efficiencies of the light of the firefly and that of incandescent electric lamps

The efficiency of the light of the carbon filament lamp is 0 43 per cent In other words of all the energy used only 0 43 per cent is converted into light The tungsten lamp has an efficiency of 1 3 per cent and the mercury arc 3 8 per cent The efficiency of the light of the firefly is 96 per cent Making the comparison in another form the carbon filament lamp has an efficiency of 83 watts per mean hemispherical candle the tungsten lamp 1 2 per candle and the metallic arc 0 [illegible] watt per candle In comparison with these the firefly has an efficiency of 0 02 watts per candle

## The Current Supplement

The current SUPPLEMENT No 1777 opens with an interesting article by the English correspondent of the SCIENTIFIC AMERICAN on the Madras Harbor Works which include a north breakwater arm 1 000 feet long to protect a new entrance E A Allcut writes on producer gas for engine fuel While means of illumination have been developing and the organized systems of distribution have ramified throughout the community there has been another and very different development going on via the growth of a branch of the science of optics which deals with the measurements of luminous values and which has been embodied in what is now called illuminating engineering Dr A D Rockwell writes on the incandescent and arc light in medicine Cartagena de Indias as it was termed by the ancient governments and now spoken of in Colombia as The Heroic City has more of the tragic and melodramatic in her history than any other town on the western continent The story of this community is told by Isaac A Manning The year 1909 marked the three hundredth anniversary of the invention of the telescope the occasion is fittingly described by Prof J L E Dreyer in an excellent article on the history of the invention of the telescope Mr Charles Richards Dodge contributes an article on forest destruction by insects and forest fires

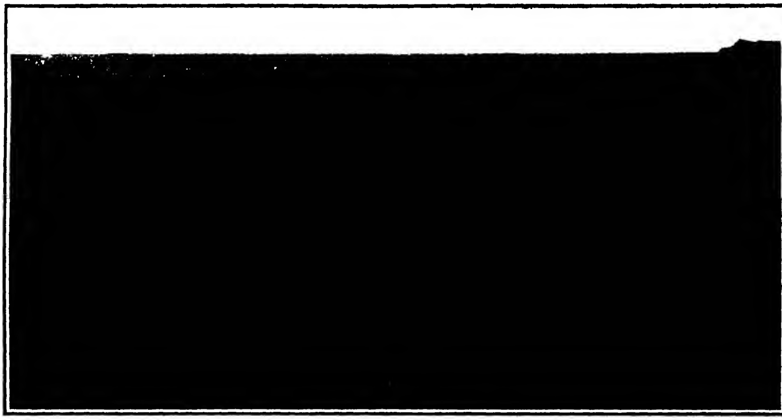
The Battle River Viaduct of the Grand Trunk Pacific Railway 67½ miles west of Winnipeg completed in December 1908 is a steel plate girder viaduct 2 772 feet long between abutments and 184 feet high from base of rail to low water or about 139 feet average height above ground It comprises a 150 foot deck truss span crossing the main part of the river channel one 70-foot plate girder span and fifty one 50-foot plate girder spans resting on twenty six steel towers Thus the tower spans are of equal length with the intermediate spans, i e 50 feet The substructure is of concrete the two river piers and most of the land footings being founded on piles

# THE NEW NAVAL HARBOR AT DOVER

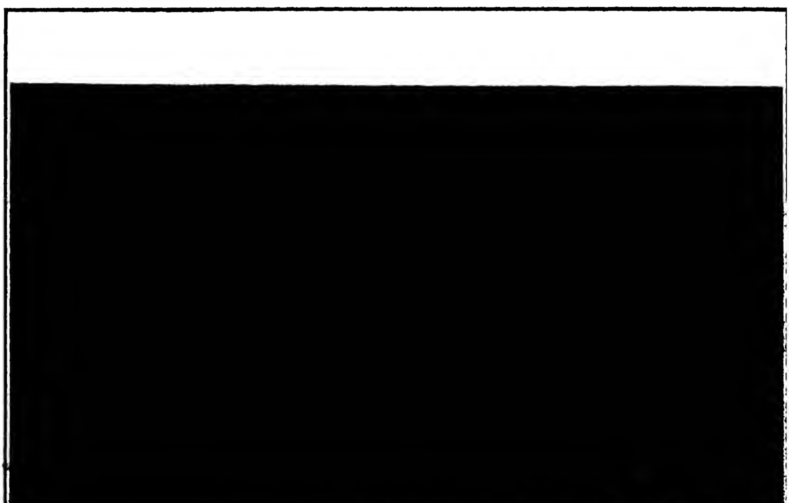
## BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

The harbor facilities of the British Admiralty have been greatly extended by the recent completion of the new and extensive works at Dover at a cost of some $*0 000 000 Dover is a point of considerable strategical importance and the necessity of some refuge for war vessels in its vicinity was advocated some hundreds of years ago Unfortunately however its geographical situation is such that it is exposed to all seas between extreme east and extreme west the full fury of which appears to be concentrated or at any rate is experienced thereat There was no convenient headland or other natural barriers of which advantage could be taken so that to convert the port into a harbor of refuge easily accessible in all weathers and which would be completely safe necessitated elaborate development works

It was in 1895 that the government decided to convert the port into a national harbor with a low water area of 610 acres, by the construction of a protection arm on the eastern side of the slight bay projecting 2 942 feet into the sea the reclamation of 3 900 feet of foreshore at the base of the cliffs the extension of the existing Admiralty pier used by the vessels engaged in the cross channel traffic with France and an island breakwater between the two extremities of the land arms 4 212 feet in length The general design of the works may be gathered from the accompanying plan



General view of the harbor from the east



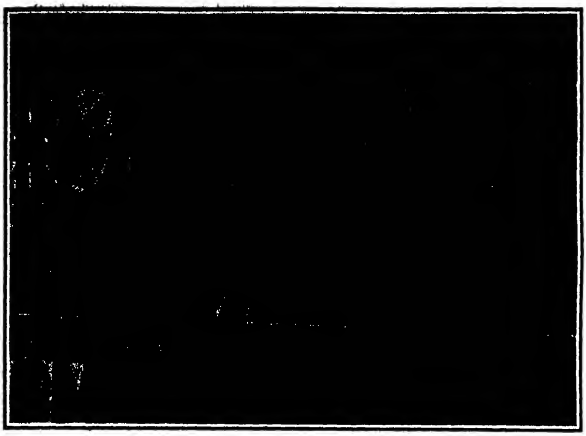
Reclaimed area in foreground of 22 acres where blocks were prepared and stacked and work in beginning [illegible]

THE NEW NAVAL HARBOR AT DOVER

in which the new construction is indicated by the sections indicated in full black. It will thus be seen that an aggregate length of 11 154 feet or over two miles of breakwater has been constructed. Access to the anchorage is secured by a gap between the western extremity of the sea arm and the Admiralty pier 740 feet in width and on the eastern side by another gap 650 feet in width. By this means the harbor can be entered in any weather tidal circulation is promoted and silting up within the inclosed area prevented. The arrangements provide for a water depth at the entrances ranging from 40 to 48 feet at low spring tides and as these tides rise nearly 19 feet it will be seen that at high spring tides the water depth is about 60 feet. Within the harbor itself a water depth at low tide up to 40 feet is available thus meeting the requirements of the largest war vessels. The contract for the undertaking was placed in 1897 with Messrs S Pearson & Sons Ltd of London to whose courtesy we are indebted for the accompanying illustrations.

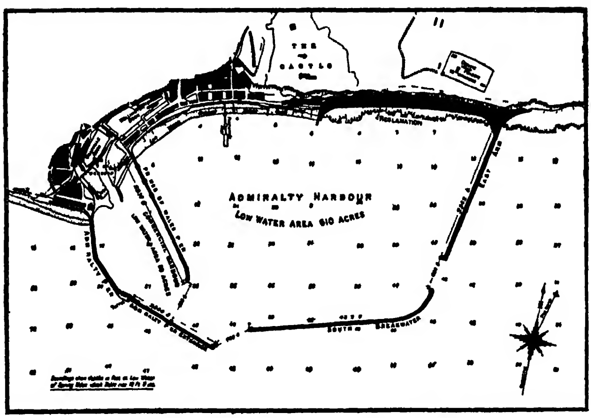
The surveys showed that the sea bed consisted of chalk chalk marl and flints so that a solid foundation could be secured for the masonry work. The work is carried out in solid masonry the blocks ranging from 26 to 40 tons in weight and composed of 6 to 1 concrete. A large block making yard was established as soon as possible upon the area reclaimed from the sea and here two 45 ton gantry cranes for handling the blocks were erected. The material for the concrete was drawn from suitable points a few miles distant and a funicular railway was built to the top of the cliff for bringing the material down to the electrically operated Messent concrete mixers which while the mixing operation was in progress traveled along an elevated track above the molds and dumped their contents where and as required. In all 260 000 tons of Portland cement was consumed in the preparation of 1 200 000 cubic yards of concrete.

Actual construction was carried out from elaborate heavy timber staging the piles of which in some cases exceeded 100 feet in length. This staging was carried to a height of 46¼ feet above low water and the deck was provided with tracks for the manipulation of the various constructional appliances. These latter comprised Goliath cranes ranging from 40 to 60 tons capacity and with a radius of 100 feet. Four of these cranes were used simultaneously on the stag



At extreme left, grab for clearing foundations at right, diving bell ready to descend At rear cranes for setting blocks below the water level

Staging at the pierhead works.



Plan of the Dover harbor works New structure shows in full black

Complete view of Dover Bay and Harbor

THE NEW NAVAL HARBOR AT DOVER.

ing. The subaqueous work was accomplished by means of diving bells Most of these had an internal measurement of 17½ feet by 10 feet and 6½ feet headroom with a weight of 35 tons when out of water and about 5 tons when submerged. They were fitted with telephonic communication and were provided with electric lighting The sea bed was first cleared by means of the grab excavators to within about 12 inches of the requisite level Then the diving bell descended and the men within completed the work and excavated to about 2 feet below the level for the foundations of the superstructure Owing to the severity of the scour and tidal action the foot of the breakwater on its outer face is protected by a masonry apron about 25 feet in width built up of concrete blocks ranging from 9 to 14 tons in weight and 3 feet 6 inches deep The bed for the apron was excavated to a depth of 2 feet by divers From foundation level up to low water the blocks are bonded together by varying the length of the blocks and are doweled in the vertical joints with 4 to 1 concrete sausage dowels of circular section Above low water the courses are bedded and grouted in 2 to 1 cement mortar while the outside blocks above this point are faced with granite the stones being well bonded into the concrete matrix

The reclaimed area lies at the foot of the cliffs and has a length of 2 300 feet by a maximum width of 350 feet the space being some 22 acres On this expanse it is intended to erect the various buildings required for repairs stores and so forth as well as two protected reservoirs for the storage of gasoline for submarines a station and depot for which is to be established her The eastern arm projects seaward from the eastern extremity of this reclaimed area in a southerly direction for 2 942 feet The construction of this southern breakwater was among the most difficult of the whole under taking owing to its exposed position and the great depth of water The average depth on this section of the foundations below low spring tides was about 47 feet the greatest depth being 53 feet Work was commenced in August 1904 and by December of the same year 480 feet of foundations was completed and the masonry brought up to the level of low water When the extension on the western pier had been completed and the plant there used was transferred to the island section work was maintained at a much higher pressure 2 000 feet of foundations being completed in a year while in two months alone 114 blocks were set in position

The width of the structures at foundation level ranges between 52 and 77 feet In the case of the eastern arm the width at deck level is 47½ feet while that of the southern breakwater is 40 feet and the Admiralty pier extension 45 feet In all cases the height of the deck level above high water spring tides is the same viz 10 feet

The extension of the existing Admiralty pier was commenced in August 1899 This arm was to be doubled in length that is to 4 000 feet and in this case owing to the existence of a revolving gun turret on the old pier head which it was decided to retain the pier had to be widened for a distance of some 690 feet in order to permit the railroad tracks serving the steam ship berths to be laid

Both the western and eastern piers are provided with a parapet 11 feet and 10 feet wide respectively the top of the former being 41½ and that of the latter 39 feet above low water The deck of the south breakwater however is quite level though similar provision can here be made if and when desired

The works have given employment to from 1 500 to 1 800 men and considering its character the accidents and fatalities have been insignificant No deaths or permanent injuries were recorded in connection with working in compressed air either in the diving bells or diving dresses During construction several exciting incidents occurred While the south breakwater was under construction the liner "Deutschland" ran into it seriously damaging its stem and removing a mass of masonry As a result several blocks had to be removed and reset To carry out this work an ingenious hydraulic ram was especially evolved comprising a horizontal cylinder having vertical rams capable of exerting a lift of 150 tons by means of which the blocks were lifted so as to be gripped by the Goliath cranes and then reset. On another occasion a vessel while entering the harbor fouled the timber staging. The collision was so violent that the two outermost cranes were carried away and considerable damage inflicted Severe delays occurred through gales. In consequence of the exposed character of the position, the full force of the southwesterly and easterly storms was experienced the waves sweeping over the works. Owing to the elaborate precautions adopted however no valuable plant was lost though at times the heavy staging showed striking evidences of the battering by wind and wave It may be mentioned that the quantity of water required during an ordinary spring tide and which flows through the two entrances is 17 000 000 tons

## A NOVEL BOILER AND FURNACE CONSTRUCTION

The furnace and boiler illustrated in the accompanying engravings possess many decidedly novel features which nevertheless have proved efficient in practice The grate of the furnace is curved up at each side of the boiler so that the forward part of the boiler is half submerged in the fuel which comes in direct contact with the boiler shell The fire burns its way up through the coal which as it is consumed feeds downward *from opposite sides of the boiler* while there is a downward draft through the coal which carries the gases to the bottom of the furnace and here they combine with air that passes through admissions at each side of the ash pit and flows between the grate bars up through the incandescent fuel The burning gases then flow through a narrow neck into a corrugated flue of large diameter which conducts them to the rear end of the boiler after which they pass through the boiler tubes to the stack Great care is taken to proportion the stack to the surface area of the tubes and flue so that the highly heated gases will pass slowly through the boiler and deliver the maximum number of heat units for the generation of steam The side grates of the furnace are provided with rocking bars which may be operated individually but they are preferably connected to a single shaft as shown in the illustration by which they may be operated all at once either by hand or mechanically to shake the coal downward toward the bottom of the grate The lowermost part of the grate is provided with a section which may be reciprocated lengthwise when shaking down the fire Ordinarily the fuel tends to feed itself down the side grates and it is merely necessary to supply it with sufficient coal at the top The fuel is thoroughly dried as it progresses downward so that there is little chance for the production of smoke despite the fact that the inner wall of the furnace consists of the water cooled boiler shell Most of the draft supplied to the furnace enters the side admissions of the ash pit which are provided with dampers to regulate the intake of air

In the spring of 1907 one of these boilers was installed in a factory at Dover N J to take the place of two boilers of 50 and 60 horse-power respectively The new boiler on the usual rating of grate area to the tube and flue area should have generated about 74 horse-power but under test it was found to develop 98 5 horse-power Formerly a stack 126 feet high was required but with a new boiler the stack was reduced to one extending but 25 feet above the boiler The boiler was 6 feet in diameter and 11½ feet long, containing 84 4-inch tubes The neck of the main flue was 9 inches wide and 54 inches long, while the flue was 27 inches in diameter.

This boiler has been in use constantly ever since and we are informed that it is giving perfect satisfaction The principal claims for it are that it requires less fuel and less attention than heretofore, while combustion is almost smokeless. Since the first installation at Dover a number of these boilers have been installed in this vicinity and appear to be doing good service.

Front elevation and longitudinal section showing the curved grate and interior details of the boiler.

A NOVEL BOILER AND FURNACE CONSTRUCTION

## A Novel Balloon Gas.

At the recent Congress of German Aeronauts at Frankfort on the Main, Dr W von Oechelhaeuser presented a preliminary communication on the results of experiments made in conjunction with the German Continental Gas Company toward the production of a new balloon gas These show the decomposition of ordinary coal gas in vertical retorts to yield in normal operation a balloon gas of a specific weight of about 0 125 so that about one kilogramme would be the lifting power of one cubic meter According to the Statutes and Regulations of the International Association of Aeronauts the buoyancy of one cubic meter of street gas has so far been calculated at 0 700 kilogramme and that of hydrogen gas at 1 050 kilogramme It is true that in connection with certain hydrogen plants a gas of a lifting power of 1 125 kilogramme is said to have been obtained and that the official figure of 0 700 kilogramme would be too low for a number of gas works, corresponding to too great a specific gravity viz. 0.44 During the Gordon Bennett ascents at Berlin a gas of 0 4 specific weight was used However on the basis of the official international figures above stated the lifting power of the new balloon gas would bear a ratio of 1 000/1 050 to the lifting power of hydrogen This would mean that a balloon of a capacity of 1 000 cubic meters would be able to lift 300 kilogrammes more than a balloon of the same capacity filled with coal gas, or else the size of a balloon with the same lifting power could be reduced by 30 per cent.

This balloon gas contains upward of 80 per cent of hydrogen while the content of methane which was the most difficult to decompose is reduced 5 to 7 per cent. The gas has only a very slight odor which is likely to prove very convenient to passengers in the case of free balloons with open charging tubes. Furthermore it contains neither benzol nor any other heavy hydrocarbon capable of attacking the balloon cover The theoretical fact that coal gas is decomposed by great heat which is underlying the process has long been known and seems to have been first discovered by Bunsen about forty years ago However the difficulties so far experienced in utilizing this reaction for the production of a light gas on an industrial scale proved far greater than had been supposed The most important point was to produce this gas during the ordinary operation of the gas works and in the same retorts in which the ordinary coal gas is generated The inventor therefore used the vertical retorts of the Dessau gas works He is now engaged in experiments intended to ascertain whether the process is adaptable also to horizontal retorts and other types

The Washington Aqueduct after forty-six years of service is in excellent condition according to the last annual report of Major Jay J Morrow, of the United States Corps of Engineers This aqueduct crosses 26 valleys on 4 bridges and 22 embankments containing culverts. The only signs of deterioration were found, it is reported in unlined portions of the conduit where a small quantity of rock had fallen from the roof and side walls. It was noted that the mortar in the brick masonry in the lined sections although inferior to present-day Portland cement, had not been washed out of joints to any great extent. Recent experiments showed that 90 000,000 gallons per day, is about the maximum carrying capacity of the aqueduct.

According to the Railroad Age Gazette, the [illegible] Railway which recently equipped thirty [illegible] locomotives to burn oil, has been unable to [illegible] supply of this fuel, and has had [illegible] converted into coal burners. The oil [illegible] failed to carry out his [illegible], it is [illegible] expense of the [illegible].

# CURIOSITIES OF SCIENCE AND INVENTION

### NEW METHOD OF CARRYING AN UNCONSCIOUS PERSON

A new method of carrying persons who are unconscious, injured, or otherwise incapacitated is being used by the New York Fire Department. Ordinarily the unconscious man is turned face downward and then lifted up on his knees after which he is placed across the fireman's shoulder. The new method consists of throwing the burden across the back over both shoulders, instead of one as heretofore. The right thigh and right upper arm of the man that is being carried are gripped between the fireman's arms and body close to the armpits. This leaves the fireman's forearms and both legs free. Formerly the fireman had the use of but one hand and arm making it a difficult matter to carry a victim down a scaling ladder. With the new method the weight of the burden is supported in a position where a maximum load can be carried with minimum exertion. The one that is rescued is firmly locked on the fireman's shoulders by the powerful muscles of the shoulders and upper arms. With both forearms and hands free the fireman can carry a burden down a vertical ladder without danger of falling and can even slide down the ladder after a little practice. To Dr Charles H Duncan whose work at one of the emergency hospitals of this city has brought him into contact with firemen and others injured at fires the New York Fire Department is indebted for this new and practical method of carrying an unconscious person.

CARRYING THE MAN DOWN A SCALING LADDER.

LIFTING THE MAN ONTO THE BACK AND SHOULDERS

### EXPERT CHAIN WHITTLING

For several years I have been collecting specimens of expert jackknife whittling. Among those who have contributed specimens is Mr George W Lockwood Long Ridge Conn. About two years ago he supplied some specimens of chain whittling from a broom stick that were far above the ordinary. For a time I regarded them as the best in existence. A little later I obtained some triple chains from a Philadelphia expert that slightly excelled those by Mr Lockwood whose attention was called to the Philadelphia work. Mr Lockwood determined to go him one better and the results were the two chains and ornaments shown herewith. These are by far better than any others I have been able to obtain. Each chain is from a piece of wood of broomstick shape the cutting without break and done with an ordinary jack knife. The "nested hourglass" sections are especially intricate and skillfully done. The inner glasses turn readily in sets or sections. As will be readily seen the links are symmetrically shaped and well finished.

"How long did it take you to make them?" I inquired.

"Time? Oh don't mention it. I didn't dare keep any record." —Edward F Bigelow

SPECIMENS OF CHAIN WHITTLING, ONE WITH "NESTED HOURGLASSES"

### A VACUUM CLEANER FOR CLEANING STREETS.

The war against dust which is now so successfully waged in houses by means of vacuum cleaning machines should undoubtedly be extended to include street cleaning. It is just as important to keep the dust down when sweeping streets and more so because street dust is always heavily laden with disease germs which are a constant menace to passersby and particularly to the street sweepers. A machine has just been perfected which works somewhat on the principle of the smaller household vacuum cleaners. The dirt and refuse of the surface over which the machine travels is gathered by rotating brushes and then by pneumatic power is sucked or lifted into conduits where the heavier parts of the refuse are extracted and deposited in closed receptacles. The fine dust which it has been impossible for mechanical sweepers as heretofore devised to dispose of is carried onward in closed conduits and wetted down so that it may be taken off in the form of silt.

The suction mechanism is operated by the engine which propels the machine the power of the exhaust being utilized in the process of separating and reducing the dust.

By actual tests recently made under the most adverse conditions this sweeper has shown its ability to clean in an hour as much street surface as the old fashioned horse-drawn sweeper will sweep or brush in six hours.

VACUUM CLEANER FOR CLEANING STREETS.

### MOTOR AMBULANCE FOR DOGS.

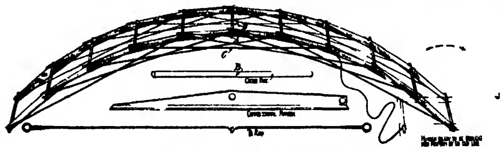
A curious motor ambulance for dogs is to be seen in the west end of London. This ambulance is the property of the Animals Hospital and is used for conveying dogs to and fro. It resembles a Noah's

MOTOR AMBULANCE FOR DOGS.

Ark in shape and is drawn by a 3 horse-power motor cycle to which it is attached by means of an ingenious coupling device which prevents the ambulance overturning when traveling around corners. The ambulance is mounted on easy springs is fitted with pneumatic tires and is well padded inside in order to minimize vibration. Being motor drawn it can do long journeys expeditiously and ailing animals can be conveyed to the hospital and treated without delay.

### A NOVEL BRIDGE CONSTRUCTION

An emergency bridge construction which appears to have considerable merit was recently exhibited before the British War Office. It comprises only three different pieces illustrated at *A* *B* and *C* in the accompanying sketch. The part *A* is the compressional member and is the only part which would have to be carried in stock. Parts *B* could be chopped out of timber growing in the vicinity while the tie rods *C* could be formed on the spot of rope or preferably wire. The construction of the bridge will be understood by referring to the members shown in dotted lines at the right hand end of the bridge. A crossbar which runs through the last compressional members of the bridge serves as a pivot for two more compressional members that are centrally fulcrumed thereon. When the two compressional members are swung around as indicated by the arrows the tie rod is drawn taut and serves to take its share of the load. In building up a bridge of this sort the outer end could be supported on a boat or pontoon while the engineers were adding the successive pairs of members to the shore end of the bridge until a sufficient span was produced to reach across the stream. The construction was designed particularly for use in reinforcing a concrete arch. When used in this way the compressional bars could be placed at the outside and after the concrete had set they could be removed for use in building the next arch.



NOVEL TEMPORARY BRIDGE CONSTRUCTION

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

NECKTIE-FASTENER AND COLLAR BUTTON.—T PAPWORTH, Portland, Ore The object of the inventor is to provide a combined necktie retainer and collar button, which can be easily inserted in and removed from a stiffly starched collar, and which in its preferred form effectually conceals the tie fastener The retainer and button is preferably made of a single flat piece of metal, although it may be produced by other means.

### Of Interest to Farmers.

BALING PRESS.—I W ROHAM, JR. Lancaster Pa This is a powerful and simple press for tobacco and like material. It can be easily manipulated by one operator and the material to be compressed can be rapidly and easily formed into compact bales which permits twine or the like to be positioned therein to facilitate the binding of the bales, and there are special locking means for holding the folding sides in position

WIRE STRETCHER.—J R. DAVIS and F S. ADAMS, Wisner Neb This stretcher is arranged to permit properly stretching wire between posts or around a corner post, and to hold the stretched wire until it is fastened in place, and without danger of causing any slack between the post and stretcher, and to allow of readily splicing adjacent wires without the stretcher being in the way of the operator making the splice

SPRING TOOTH CULTIVATOR.—G G BARDEN, Cypress Ala This cultivator is of the type that presents cross bars to which the spring teeth or hoes are attached By adjusting the position of these bars the arrangement of the teeth can be changed as desired The adjusting mechanism will insure that the bars will hold themselves perfectly rigid in their different adjusted positions.

### Of General Interest.

COAL-BASKET.—H G MITCHELL, New York, N Y The aim in this improvement is to produce a basket especially adapted to be formed of duck, canvas or similar stout fabric, and which is provided with a reinforcing frame giving the finished basket strength and durability for handling coal or the like Feet project below the bottom of the frame to receive the principal part of the wear across the earth or floor

ELECTRIC FURNACE FOR THE CONTINUOUS EXTRACTION OF ZINC FROM ITS ORES.—E F CÔTE and P R PIERRON, 24 Rue Sully, Lyon, France The object in this improvement in electric furnaces is to permit zinc ores, preferably poor blends, to be treated in a continuous manner for extracting the metal therefrom, and permitting the heating of crude blends without it being necessary to previously roast them in order to transform the sulfid into oxid.

STOPPERING FOR BOTTLES INTENDED TO CONTAIN VOLATILE LIQUIDS.—J BENGUE, 47 Rue Blanche, Paris, France This device enables a capillary orifice of larger diameter and the capillary orifice employed for delivering ethyl chlorid in medical practice to be stoppered. It may be utilized for ethyl chlorid or other volatile products either mixed or not with medicinal substances or with perfumery essences.

AREA FINDING APPARATUS.—ARTHUR C FARRMAN, Norfolk, Va. The invention comprises a flat steel plate that is magnetized and a number of soft iron balls. The drawing upon which the area is outlined is placed over the plate. The area outlined is then filled with the iron balls. The magnetized plate causes them to cling to the plate and to each other The balls are then taken out and placed in a measuring frame, and the number of square inches occupied by the balls is ascertained

EYE-SHADE.—J A BLACKSTOCK, Seattle, Wash The object of this invention is to provide a shade which will effectually prevent light rays from reaching the eyes, and it is especially adapted for use by people desiring to sleep in the daytime in order to obviate the necessity of darkening the room.

GASTROSCOPE.—M SUSSMANN, Berlin, Germany This gastroscope comprises a horizontal and a vertical part. The latter when flexible is easily introduced through a feed pipe into the stomach, after which it is straightened for the examination This part can be turned through any angle After examination the vertical part is turned into its flexible state, so that it can be easily drawn out

### Heating and Lighting.

ADJUSTABLE HANGER FOR LIGHTS.—H J HINDS Hillyard Wash The purpose of the inventor is to provide novel details of construction for an adjustable hanger that is particularly well adapted for the suspension of a lamp or the like from an overhead support, and enable the vertical adjustment of the light at a desired height

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

Journal box lubricating device, C. B. [illegible]
Junction box, T. R. Murray [illegible]
Keyboard operating mechanism, Knudsen & Barth [illegible]
Key fastener, C. O. Shaub [illegible]
Key receptacle and chain, combined, A H Field [illegible]
Kiln, T M Wilson 946,086 to [illegible]
Label, bottle I Levi [illegible]
Lace machine for producing braided or plaited, H Bucher [illegible]
Lamp, arc, Harthan & Dalton [illegible]
Lamp, arc W D Ryan [illegible]
Lamp bus carriage R. B. Cole [illegible]
Lamp burner, E. Y Buchanan [illegible]
Lamp incandescent petroleum, M Malkiel [illegible]
Lamps, adjustable support for vapor, S. B. Flickinger [illegible]
Lamps, apparatus for exhausting incandescent, L. O Wadsworth [illegible]
Lamps, carbon feeding mechanism for arc, [illegible]
Lamps, obtaining metallic attachments for incandescent, [illegible]
Lamps, pull socket for incandescent, H. T Paiste [illegible]
Last, shoe A G. [illegible]
Latch, gate G. S. Mitchell [illegible]
Lathe, turret, F K. Hendrickson [illegible]
Laundry iron, electric, E. H. Richardson [illegible]
Lawn sprinkler, E. P Kriger [illegible]
Ledger, loose leaf, G. A. Hofstetter [illegible]
Lettering device, Black & Morris [illegible]
Lever builder, D. J La Rosa [illegible]
Level for measuring angles and inclinations, spirit, A. [illegible]
Life preserver, J. Friedman [illegible]
Lightning arrester, F. H Thomas [illegible]
Liquid heating apparatus, F T [illegible]
Liquids from barrels into storage receptacles, apparatus for discharging, [illegible]
Loading machine, G. Kraus [illegible]
Lock. See Door lock.
Lock, C. R. Lowe [illegible]
Locomotive ash pan, H A. Hoke [illegible]
Locomotive driving boxes and the like, liner for, [illegible]
Locomotive engine, H. H. Vincent [illegible]
Locomotive strainer, Bowman & Harmeyer [illegible]
Loom connecting rod and lubricating device, [illegible]
Looms, [illegible] W Wattie [illegible]
Lubricator, Frick & Thompson [illegible]
Mail delivery apparatus, [illegible]
Mail distributing rack, [illegible] Carpenter [illegible]
Mail pouch receiving and delivering [illegible]
[illegible]

Mop, T Evans 945,772
Music chart, mechanical, E. L. Turner 946,391
Musical instrument attachment, O H Avis 946,340
Musical instrument, automatic, F Welin 945,[illegible]
Musical instrument, automatic, F Welin 945,897
Musical instrument, mechanical, R. S. Votey, reissue 13,976
Musical instruments, automatic playing attachment for, F Welin 946,395
Musical instruments, controlling lever and fall board for automatic, F Welin 946,399
Musical instruments, pedal mechanism for, F Welin 946,[illegible]
Musical instruments, tracker board for automatic, F Welin 946,[illegible]
Musical instruments, valve for pneumatically controlled, F Welin 945,[illegible]
Name register, F W Leatheuser 946,446
Navigator's calculating instrument, B Hill, Jr 946,042
Necktie, H Martin 945,970
Necktie holder for negligee shirts, O K Ruehs 946,[illegible]
Needle, F H Schomberg 945,[illegible]
Nest, interchangeable hen's, H Beutteker 946,[illegible]
Nitrocellulose bodies, making horny, V Vender 946,[illegible]
Nozzle holder, C F Mohrhoff 946,[illegible]
Nut lock, H E Kittredge 946,[illegible]
Nut lock, Reinoehl & Weaver 946,[illegible]
Oil burner, H R Stills 945,[illegible]
Oil burner, H Duke 945,[illegible]
Oil burner, J A Mahr 945,[illegible]
Oil or vehicle for paints, colors, and pigments, A Hahn 946,136
Oiler, tramway, E H Hall 945,[illegible]
Olive grinding machine, A V Bills 946,[illegible]
Ore separator, F H McGowan 945,[illegible]
Ore separator, magnetic, G H Ohrn 946,[illegible]
Oxygen administering tank, C von Ach 946,[illegible]
Package for playing cards, S S Sanguinette 945,[illegible]
Packing box, W I Cook 946,017
Packing case, A G Sherman 945,[illegible]
Packing for stuffing boxes, G Lingner 946,[illegible]
Parking rod, H J Armstrong 946,001
Pan. See Dust pan
Paper bag machine, F H Strassburg 945,944
Paper bands, apparatus for producing combination of holes in, H Ehrhardt 946,094
Paper folder, L A Nichols 946,[illegible]
Paper sheet feed mechanism, F Gilroud 946,[illegible]
Paper tube machine, F C Osborn 945,[illegible]
Pasteurizing apparatus, A A Lindstotte 946,[illegible]
Patterns, laying out, C F Schilbe 945,814
Pedal, A F & C H Norris 945,[illegible]
Pen, fountain, R H Hallock 946,[illegible]
Pen, marking, J W Newman 946,[illegible]
Pencil holder, H E Hyman 946,[illegible]
Pencil sharpener, W H Behe 946,[illegible]
Percolator overflow, R A Heitzman 945,[illegible]
Perforating and binding machine, C F McGhee 946,688
Photography, making screens for color, C Spath 946,470
Piano, E M Bent 946,[illegible]
Piano, automatic player, E F Welte 945,[illegible]
Piano hammer heads and shanks, tool for extracting, A H Webster 946,[illegible]
Piano hammer rail and means for operating the same, Bard & Winter 946,006
Piano pedal lock, J T Mayer 945,[illegible]
Pianos, equivalent mechanism for, F Welte 945,[illegible]
Picking machine, J R Rhode 945,[illegible]
Picture post card display device, A R Bright 946,407
Pie crust rimming machine, O Colborne 945,918
Pie making machine, D K Allison 946,[illegible]
Pin switch, H S Goughnour 946,[illegible]
Pipe joint, flexible, A C Firin 946,[illegible]
Pipe line, clearing device, J Maule 945,971
Pipe or hose coupling, J H Phillips, Jr 946,[illegible]
Pipe section and joint for corrugated, F M Dusk 946,207
Pipe wrench and cutter combined, O C Brow 946,102
Planer, W K Infelder 945,[illegible]
Pliers, insole clipping, G A Beals 946,[illegible]
Plow, W T Trimmer 945,[illegible]
Plow, A G I 946,461
Plow sulky, F W Pauling 945,[illegible]
Plow, joint for attachment, T R R 945,[illegible]
Plug, attaching, A G Wilcox 946,[illegible]
Pocket seal, J W Withey 946,[illegible]
Pole, vent and, W H Daugherty 945,784
Power distributing system, W J R Emmet 945,925
Pressing machine, Schirmer & Lahr 946,[illegible]
Pressure regulator, R Repp 946,[illegible]
Primary battery, T W Lyon 946,[illegible]
Printing, E Boreart 946,326
Printing device, W E Armstrong 946,[illegible]
Printing machine, A R Fink 945,[illegible]
Printing machine, A R Fink 946,741
Printing press feed mechanism, J A Banks 945,[illegible]
Pump, air, A O Williamson 946,[illegible]
Pulverizer, T O Wilbur 946,410
Pump for motor vehicle tires, inflating, M Rohl 946,101
Pump, rotary, E Hughes 946,[illegible]
Pump, steam, J H Gamble 946,080
Punch, ticket, A P Odell 945,861
Punching and forming machine, J C Thompson 946,874
Push button, safe receptacle, N Marshal 946,909
Quilling frame, F D Mahony 945,965
Rack. See Mail distributing rack
Rail chair and fastener, J A Morehouse 946,054
Rail guard, E A Basley 946,425
Railway signal, gas for lurking graves and weeds, F M 945,806
Railway block signal system, Fels & Gray 946,4[illegible]
Railway brake mechanism, automatic, and adjustment device for, Harrington & Long 946,[illegible]
Railway crossing, suspended, B H Hickman 946,749
Railway electric signaling apparatus, W J Cook 946,[illegible]
Railway rail, bair W F Tlo 946,[illegible]
Railway rail or track, E Treiser 946,611
Railway, street, suspension, Butler & Eckman 945,751
Railway switch and operating means therefor, H & R A Boyer 946,[illegible]
Railway switch, suspension, Butler & Eckman 946,[illegible]
Railway tie, J Booth 946,[illegible]
Railway tie, metallic, W H Sheer 946,[illegible]
Railway trains, automatic stopping mechanism for, W J Wilgus 946,[illegible]
Railway trains, automatic stopping mechanism for, W J Wilgus 946,415
Railways, guard covering for third rails of electric, C Kruse 945,[illegible]
Range boiler, V Wilhelmi 946,[illegible]
Range transmitter, L Hall 946,[illegible]
Razor strop holder, G R Ma[illegible] 946,[illegible]
Reamer, expanding, J H Matthews 946,[illegible]
Receivers, means for exhausting, M von Recklinghausen 946,[illegible]
Receptacle, metallic, C W Brown 946,[illegible]
Reclining chair, Fowler & Sadler 946,[illegible]
Recording instrument, pencil or stylus holder for, J L Kandler 946,[illegible]
Reel, machine, McLane & Ripp 946,[illegible]
Refrigerator, J Goldfeld 946,[illegible]
Relay or electromagnet, electrical, H E Clemens 946,[illegible]
Resistance device, G Heckham 946,[illegible]
Resistance unit, E Thomson 946,[illegible]
Revolver, automatic, G Vander Haeghen 946,[illegible]
Revolvers, knife attachment for, H H Hull 946,[illegible]
Road construction, H Amies 946,[illegible]
Rock drilling machine, R B Winters 946,[illegible]
Rock drill, Fourtee & Mattl 946,[illegible]
Roll, brake, E Moon 946,[illegible]
Roller. See Matting roller
Roller support, J Mayo 946,056
Roof ornament, J E Bowers 946,[illegible]
Rotary engine, G F Ball 946,[illegible]
Rotary engine, J C Williams 946,[illegible]
[illegible] 946,[illegible]

## Instructive Scientific Papers
### ON TIMELY TOPICS

**Price 10 Cents each by mail**

**ARTIFICIAL STONE.** By L. P. Ford. A paper of immense practical value to the architect and builder. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

**THE SHRINKAGE AND WARPING OF TIMBER.** By Harold Busbridge. An excellent presentation of modern views; fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

**CONSTRUCTION OF AN INDICATING OR RECORDING TIN PLATE ANEROID BAROMETER.** By N. Monroe Hopkins. Fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

**DIRECT VISION SPECTROSCOPES.** By T. H. Blakesley, M.A. An admirably written instructive and copiously illustrated article. SCIENTIFIC AMERICAN SUPPLEMENT No. 1493.

**HOME MADE DYNAMOS.** SCIENTIFIC AMERICAN SUPPLEMENTS 161 and 600 contain excellent articles with full drawings.

**PLATING DYNAMOS.** SCIENTIFIC AMERICAN SUPPLEMENTS 720 and 793 describe their construction so clearly that any amateur can make them.

**DYNAMO AND MOTOR COMBINED.** Fully described and illustrated in SCIENTIFIC AMERICAN SUPPLEMENTS 844 and 865. The machines can be run either as dynamos or motors.

**ELECTRICAL MOTORS.** Their Construction at Home. SCIENTIFIC AMERICAN SUPPLEMENTS 759, 761, 767, 641.

**Price 10 Cents each, by mail**

Saw tool, C L Johnson 946,[illegible]
Sawdust conveyer, J Clam 946,[illegible]
Sawing or felling trees, machine for, M. L. Flynn 945,[illegible]
Sawmill guard, B H Chandler 946,[illegible]
Scale illuminating device, computing, C B Longstreth 946,447
Scale, proportional, N M Blair 946,[illegible]
Scale, weighing, J M Triner 946,[illegible]
Scissors, O N Wikander 946,414
Scissors, F O Hemme et al 946,441
Screen, C C Armstrong 946,[illegible]
Screw cutting attachment, F M Anthony 946,[illegible]
Screw seat, O J Anderson 945,727
Screws, guard for set, W H Ackerman 945,[illegible]
Seal, H E Irwin 946,[illegible]
Seal, car door, W Reichert 945,804
Seal fastening, T E Murray 945,[illegible]
Seal fastening, T E Murray 945,[illegible]
Seal for holding knots, metallic, C S Brasington 946,[illegible]
Seal or packing liquid, K Ahlquist 945,900
Sealing and stamp-affixing machine, envelope, B J Brasseur 945,744 945,[illegible]
Sealing apparatus, envelop, B J Brasseur 945,743
Sealing device for bottles, Cardell & Bergstrom 946,[illegible]
Sealing machine, envelop, B J Brasseur 945,740
Sealing machine, envelop, C Robbins 946,071
Separator, W H Rice 946,[illegible]
Sewing machine, F W Merrick 946,[illegible]
Sewing machine attachment, L Boyd 946,[illegible]
Sewing machine cording attachment, A F Day 947,[illegible]
Sewing machine embroidery or ornamental stitch, W N Parkes 946,150
Sewing machine looper mechanism, hooked needle, F W Merrick 946,064
Sewing machine take up, J Diehl 941,019
Shaft spring, J F Ruslan 941,[illegible]
Shaft support, J Ehrenman 946,022
Shaper and planer, H E Rhoads 946,[illegible]
Sharpening device for blades of lawn mower knives, W F Miller 946,[illegible]
Sharpening machine, file, C M Paterson 945,[illegible]
Shearing machines, electrically controlled squaring mechanism for, R. Miles 946,487
Sheet manipulating device, G E Beyer 946,100
Sheet metal finishing, galvanized, A Niedringhaus 946,[illegible]
Shirt blouse, C K Ruebe 946,400
Shirt sleeve, A Paradis 945,[illegible]
Shoe stretcher, J C Griso 945,[illegible]
Shoulder brace, R Nesbitt 945,[illegible]
Shovel. See Steel shovel
Shovel and sifter combined, L H Chamberlin 945,754
Show case, Allnut, Bradford & Mosting 945,[illegible]
Show case, show window and the like, C M Conley 946,018
Sifter, door, M E Higgins 946,[illegible]
Sight feed, J C Hill 946,[illegible]
Signaling apparatus, electric to the motor, J G Nolen 946,[illegible]
Signaling apparatus, submarine, Wood & Barden 946,[illegible]
Signaling mechanism, F M Dewey 947,[illegible]
Signaling system, J J Hall 946,431
Silo, G Mocks 946,[illegible]
Sizing screen, revolving table, I N Warner 946,[illegible]
Skate, G B Neborth 947,[illegible]
Skate, extensible, W B Alden 946,[illegible]
Skylight, T Watts 945,[illegible]
Sliver regulator, J N Wilson 945,[illegible]
Sill holder, W H Schroeder 946,[illegible]
Smelting sulphur ores, H Fleming 945,[illegible]
Snap machine, Reid 946,[illegible]
Socket spindle, I H Millsap 946,[illegible]
Sound amplifier, N Baldwin 946,[illegible]
Sound box, J Coleman 946,[illegible]
Sound box, analyzing, G L Coleman 946,014
Sound producing device, H B Gale 946,[illegible]
Sound reproducing machine, A B Madison 946,243
Spark plug, O C Wheeler 945,[illegible]
Speaking tube, acoustical, J H Isaacs 945,[illegible]
Speed mechanism, valve, H W Briggs 945,071
Speedograph, speedometer and gear combination, H J Ris 946,176
Splicing and twisting rings, holding means for, F A C Rhodes 945,806
Spinning and weaving, process in the metal fibers contained in straw grass, or bast and the like, process of operating for, F A Behnke 946,[illegible]
Spinning device, W R Ullman 946,[illegible]
Spinning machine, F H Culver 946,[illegible]
Splashing guard, Brennan & Peabody 945,907
Spring switch, A B Murray 946,[illegible]
Spring wheel for vehicles, W A Kerman 945,[illegible]
Stamp affixing machine, W E Rausch 945,[illegible]
Stamp hinge and sealing lever, Ironi & Talbot 945,[illegible]
Stand. See Cycle stand
Steam power, operated machine for, W B Pitt 945,[illegible]
Staple trailing, power, sl machine for, W Fitt 947,770
Steam engine, F J Armstrong 946,[illegible]
Steel wheel (rolled), W T Judy 946,[illegible]
Steel tramp, rolling device for, R H Wolf 946,[illegible]
Stereo pin, a sorter, H W Kerr 946,[illegible]
Stereo type and stereograph, Packer & Payne 941,[illegible]
Stereotype plate casting machine, J Nail, W H Drum 946,[illegible]
Stereotype plate, anti, g mechanism, J W 946,[illegible]
Steam & Wall, J H 946,[illegible]
Stop, wheel, form for lug art final, R J 946,100
Stop, for railway, Keighley & N 946,[illegible]
Stopper, fan, B I 946,[illegible]
Stove, J H Barritt 946,[illegible]
Stovepipe rise, C T Harms 946,[illegible]
Stretcher, making, ... H 946,[illegible]
Sulfur mine, G Strance et al 946,[illegible]
Swell and plunging arrester, ... 946,[illegible]
Wood & Thomas 946,418
Switch, W M R 946,[illegible]
Switch, bond, C F Andersen 946,[illegible]
Synchronizing, alternating, I P M I 946,[illegible]
Syringe, T M Nelson 946,[illegible]
Table, C H Ima 946,[illegible]
Tail rail, A T R 946,[illegible]
Tailor's guide, J Augusten 946,101
Taking machine, R J 946,[illegible]
Talking machine, ... for the ... and boxes of, G N Ramage 946,[illegible]
Tanning, ... A Bossert 946,[illegible]
Target trap, W H Hindaul 946,[illegible]
Telegraphic transmitter keyboard, E F Kleinschmidt 946,172
Telegraphy, spark, J R Rome 946,166 to 946,[illegible]
Telephone adjuster, A Rex 946,[illegible]
Telephone line apparatus, C D Ewing 946,[illegible]
Telephone lock, G Whyte, C W Throckmorton 946,297
Telephone metering system, H Mason 946,[illegible] 946,382
Telephone transmitter, F W Larsen, ... Hoefer 946,410
Tensile device, S W Wartwell 941,[illegible]
Thread-tying tool for wool, C S Snyder 946,077
Ticket holder, H I Kiley 946,241
Ticket seller, K Hepper 946,[illegible]
Tie, R Nock 946,[illegible]
Tie and lumber bunk, H T Ieterson 945,864
Tile cutting machine, feed mechanism for, J P Boswell 946,[illegible]
Tile roofing, E D Watson 946,177
Tire heating device, J A Mahr 945,[illegible]
Tire heating device drive wheel, J A Mahr 946,[illegible]
Tire wheel, H H Hodgson 946,044
Tobacco moistener, A Falk 946,[illegible]
Tobacco pipe, J F Miles 946,[illegible]
Tongs, pipe, Gillespie & Carey 946,[illegible]
Tool combination, E & I F Peterson 946,[illegible]
Tool pneumatic, H Schwelm 946,[illegible]
Towel, L Callahan 946,[illegible]
Toy, R Mahl 946,[illegible]
Toy, J L Clarke 946,[illegible]
Toy figure, J T Berry 946,[illegible]
Track sanding apparatus, I A Gibbs 946,[illegible]

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

NEW YORK, SATURDAY, JANUARY 29th, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## WAVE VERSUS SHIP

WAS it a last despairing protest of Old Ocean, when he lifted his giant hand in the blackness of the night of January 10, and smote the "Lusitania" a blow which racked and splintered her lofty bridge and pilot house, 75 feet above the sea, and crushed down her forecastle deck and decks beneath, giving them a permanent depression of several inches? For time was, and not so very long ago, when the sea was the undisputed master of the ship, and whenever Neptune saw fit to open the vials of his wrath and send his league-long rollers across the deep, the proudest ship of the day must needs stop at his bidding, if she did not indeed turn and run before the fury of the blast. Of late years, man, by virtue of his knowledge and mechanical skill, has been building in ever increasing lengths and breadths, and with such ceaseless enlargements of bunker and boiler room—he has so multiplied horse-power, and has called to his aid so many ingenious contrivances for speed and strength and safety, that old Neptune must for many a decade past have foreseen the humiliating day when he could no longer hold the destinies of the bold sea voyager in his hand, and no longer say to him, Thus far, and thus slowly shalt thou go.

Following the hint of ultimate victory which was supplied by the "Lusitania" and "Campania," came that wonderful ship of the Hamburg American Line, the "Deutschland," and the even larger and more powerful "Kaiser Wilhelm" and "Cecilie" of the North German Lloyd, and with the advent of each giant vessel, man's growing mastery of the ocean was shown in ever increasing speed, and a closer approximation in times of departure and arrival to the regularity of transportation on land.

It was reserved for the steam turbine to supply the last mechanical device which was to give to man in his age-long struggle with the elements a weapon of complete victory, for in the combination of size and strength and power afforded by the latest turbine liners there has been developed a ship which has demonstrated its ability to drive at full speed and all day long into the heaviest seas that the stormy North Atlantic could pile across her path. The writer will not soon forget a notable day some two winters ago, when the "Lusitania," in weather which varied from a gale to a full hurricane, averaged for the twenty-four hours a speed of between twenty-six and twenty-seven land miles an hour. During the tumult of that tremendous struggle ten-ton anchors were shifted, it is true, and steel derrick booms were swung athwartship and twisted as if they were no stouter than a boy's tin whistle. Yet the ship steamed into port practically intact, and with not a rivet started in the whole fabric of her hull.

Ordinarily a transatlantic liner will drive her way against a westerly gale voyage after voyage, with no more serious hurt than the bending of a stanchion or the breaking of a pane of glass in the pilot house. But once in a long while there may come a combination of seas which are so related to the length of the ship that she may be riding down one wave, with her bow buried deep and her forecastle deck awash, just as her stem drives into a roller, steep of front and of vast height. Then it is that the structure of the ship meets its moment of supreme trial, and not even the officers 75 feet above water, are safe from the full impact of a solid Atlantic sea.

On the Monday night in question, because of the tempestuous weather, the glass windows in the pilot house had been lowered and the storm windows built of solid wood, with a small heavy glass port light in the center, had been raised. The stern of the vessel was lifting high on a receding sea, and the forecastle deck was awash, just at the moment that a wave of gigantic proportions loomed up at the bow. From the fact that the solid water swept entirely over the pilot house and the compass stand upon its roof, which latter is at least 80 feet above the normal waterline, this wave must have been some 35 feet high measured from the trough. The sea was breaking and therefore the mass of water must have had considerable forward momentum. The ship itself was running at half speed, and met the sea at a speed of from twelve to thirteen knots. When the mass struck the breastworks and pilot house, every one of the stout wooden storm windows was burst in, the woodwork being stripped clean to the sashes, and the stout steel framing between the windows was forced several inches into the pilot house. The sea swept onward, driving a piece of the woodwork bodily through a hardwood casing containing a portion of the fire-fighting apparatus. The quartermaster was borne back against the bulkhead behind, carrying in his hands the wheel which was torn from its standard. The mass of water then swept into the officers' wardroom and staterooms, filling them breast high with water—and this, be it remembered, at an elevation of 75 feet above the normal sea level.

Now, since the ship is some 80 feet broad at this point, and the distance from the pilot house to the stem must be at least 150 feet, and since, in order to roll over the pilot house, the waves must have been some 35 feet in height, at least 4,000 tons of water must have swept over the forecastle deck—as anyone with a pencil and pad may easily figure out for himself. It cannot be possible that the wave fell with much vertical impact, or the decks would have crumpled up like an egg shell, but the momentum was sufficient to crush the forecastle deck and the three decks below a few inches down into the body of the ship, leaving them with a permanent set. Dramatic evidence of the enormous stresses to which the ship was subjected is afforded by the stanchions and solid steel bulkheads below the deck, which, in some places, buckled out of the vertical as they yielded beneath the load above. Had the "Lusitania" not been built of special strength to stand such buffeting as this, the results might easily have been very serious indeed, and we are inclined to agree with her captain in his belief that many smaller and less stoutly built ships, which have disappeared utterly at sea, may have been sent to the bottom by the crushing in of their decks under so-called "tidal waves" of these dimensions.

## INDUSTRIAL FELLOWSHIPS IN UNIVERSITY WORK.

THE University of Kansas has inaugurated a system of Industrial Fellowships, which is based upon a broadly similar practice that has already been followed to some extent in Europe. Some three years ago Prof. Duncan, of the Department of Industrial Chemistry, directed the attention of manufacturers to the necessity for greater technical efficiency, and suggested that this might be promoted if the manufacturing interests in the field of industrial chemistry co-operated with the universities by establishing fellowships for research in certain specified directions. At the present time eleven fellowships have been established, of which eight are now in operation. A full discussion of the scheme will be found in the current issue of the SUPPLEMENT, but the general scope of the movement may be gathered from a consideration of the following fellowships which are among those which have been already established:

A Fellowship for an investigation into the chemistry of laundering, with a view to saving laundered fabrics, $500 a year with 10 per cent of the profits.

An investigation into the Chemistry of Baking, established by the National Master Bakers' Association, with the object not only of improving the chemistry of bread, but of providing for the association of a trained expert on whom they could thereafter rely, $500 a year together with a sum to be settled by arbitration.

An investigation into the relation between the optical properties of glass and its chemical constitution, $1,500 a year and 10 per cent of the profits.

The discovery of new utilities for ozone, $2,000 a year and 10 per cent of the profits.

The general form of the agreement calls for an investigation to which the holder of the fellowship gives his whole time and attention, with the exception of three hours a week, which he devotes to work of instruction in the Chemical Department of the University. The Fellow, who is appointed by the chancellor and other officers of the university, must have a reputation in research, must be a member of the university, must work under the direction and advice of the Professor of Industrial Chemistry, and must forward through him to the industrial company, the donors of the fellowship, periodical reports of the progress of his work. All discoveries made by the fellow during the tenure of the fellowship become the property of the industrial company, subject to the payment to the fellow of 10 per cent of the net profits. In the event of any disagreement between the donors and the holder, the chancellor of the university, or his appointee, is mutually accepted as arbiter.

The advantages accruing from these fellowships, according to Prof. Duncan, are that the university gains increased opportunities for promoting research, that it obtains three hours a week of gratuitous and skilled instruction, that the manufacturer obtains the advantages of vastly increased laboratory facilities and full library facilities (for lack of which factory research has been most seriously hampered in the past), that the manufacturer has consultative advantages, since the fellow appointed is at liberty to question specialists in the different fields of chemistry, that the manufacturer is freed from supervision of the work of research, and that on the termination of the fellowship he obtains, if he so desires, the services of a man educated to this particular need. As regards the fellow, he co-operates in the advantages above ascribed to the manufacturer, he obtains an inside knowledge of factory processes, and he is freed from the petty interferences and jealousies of shop employees and the "pot shop" judgments of factory officials. Moreover, if he makes good, he obtains a position for which his training during the fellowship renders him peculiarly qualified.

Finally, since at the end of the three years' term, all work done under any fellowship must be published free to the public, the latter becomes one of the most important beneficiaries of the new system. The insertion of this last clause was at first resisted by some of the manufacturers, but in the end the donor, when it was pointed out to him that a really progressive manufacturer would find that three years would give him a sufficient start of competitors, withdrew his objections.

## THE MOON AND RADIO-ACTIVITY

THE probable influence of the moon's movement upon the radio-activity of the air is brought out by M. Paul Besson in a paper presented to the Académie des Sciences. We find that different authors show great variations in the radio-activity of the air, and M. Besson concludes that this radio-activity comes from the ground, as Elster and Geitel also suppose. He made experiments in the summer of 1908 and 1909 and showed that the variation in the activity of mineral water varied with the atmospheric pressure, being highest when the pressure lowered. Other authors observed the same fact. When the barometer descends the emanation from the soil increases, and the contrary. But he noticed other variations which were unaccounted for, and thought that they might come from the tidal movement of the earth's crust, which was shown in a striking way by M. Charles Lallemand of the Bureau of Longitudes. When the moon passes the meridian it causes a tidal wave in the earth's crust, and the emanation from the soil is maximum at this moment, and *vice versa*, at least as may be supposed. The author's observations lead to the following conclusions. As regards atmospheric pressure alone for a one-hour test which is constant with relation to the moon's passage at the meridian and thus excluding the moon's influence, the radio-activity increases when the atmospheric pressure decreases, as above noted. As to the influence of the moon, we find that at a constant barometric pressure, the activity is maximum for the passage of the moon at the meridian and minimum for the passage at the other side. The author hopes to make a more complete series of observations in order to establish his hypothesis. If the law of variation of the emanation coming from the earth could be established, we would ascertain the principal cause of the variation of the air's radio-activity. Should it be found that the moon's movement caused changes in the radio-activity of the air, we would have the proof that the moon has an influence on the changes of weather, according to the popular belief, this being caused by multiplying or lessening the centers of condensation of water vapor, outside of air pressure effects and others.

Mr. T. H. Svedberg has succeeded in obtaining by ultra-violet radiations, colloidal solutions of various metals in different liquids. The metal to be pulverized should be perfectly freed of any surface oxides. After being covered with the solution in a flat bowl, it is exposed from above to the radiations of a quartz glass mercury lamp. After a few minutes the liquid, when observed in the ultra-microscope, shows the characteristic aspect of a colloidal solution. Different metals and solutions show a rather different behavior. Thus silver, copper, tin and lead were found to be quite readily pulverized colloidal solutions, whereas platinum, aluminium, and cadmium show only a very slight, if any, pulverization. The experimenter carried out investigations with lead and silver not only in water, but in a number of other solutions, and showed that the magnitude and number of particles may be very different, according to the conditions of the case, pulverization being dependent on the nature of the solvent.

## ENGINEERING.

We note that the Indiana State Railway Commission has recently issued an order requiring that all locomotives except those that are engaged in switching be equipped with headlights of not less than 1,500 candle-power

A train consisting of 120 coal cars, each carrying 55 tons of coal, was recently hauled a distance of 125 miles over the Virginian Railway in 8 hours, 11 minutes. The locomotive, which is of the Mallet type, weighed, with the tender 481,000 pounds, and the total weight of the train was therefore over 9,100 tons.

In view of the continual improvement which is taking place in the marine turbine the outlook for the early installation of the marine gas engine in ships of large power is not very promising Perhaps the future of the latter lies in the direction of small high-speed engines generating current to be used on slow-speed electric motors direct connected to the propeller shafts.

In the recent placing of a memorial window in Westminster Abbey to Sir Benjamin Baker, a fitting tribute was paid to a great engineer and a precedent was established which in this age of technical achievements must meet with universal approval The tablet reads "In Memory of Sir Benjamin Baker, Civil Engineer, Forth Bridge, Assouan Dam, B 1840, D 1907" It is probable that the series of windows, of which this forms one, will be reserved for commemoration of other famous engineers.

The warship has already surpassed the ocean liner in speed and she is rapidly overtaking her in size The new British armored cruiser "Lion" will be about as long as the "Oceanic' and of the same beam as the "Mauretania." At full speed, propelled by 70,000-horse-power turbines, she will make from 29 to 30 knots. With her eight 12-inch guns carried high above the water line, her four smokestacks and two tripod masts, this great ship will certainly present a most formidable appearance

The really extraordinary increase in the power of reciprocating engines due to utilizing the exhaust in a low pressure turbine will be understood when it is borne in mind that in expanding steam from say 150 pounds to a 28-inch vacuum, over 90 per cent of the expansion and over 40 per cent of the reduction in temperature occur below atmospheric pressure, or say, from about one pound gage to about one pound absolute It took the low-pressure steam turbine to recover the heat energy thus lost in the exhaust

We understand that the British government is favorable to the construction of a ship canal across Scotland from the Firth of Forth by way of Stirling, Loch Loman, and Loch Long, to the Firth of Clyde The plan proposed calls for 85 miles of lake navigation It is estimated that the work can be completed in nine years at an expenditure of about $100,000,000 If the canal be built to conform to naval requirements of a minimum depth of 36 feet and bottom width of 148 feet, with locks to match, the government will be prepared to co-operate with private enterprise

The improvement in roadbed, rolling stock and protective signaling on American railroads is shown by the Bureau of Railway News of Chicago, whose returns show that 340 roads operating over 153,000 miles of railway have not killed a passenger during a period of one year. It is true that toward the close of 1909 there was one of those curious epidemics of accidents which cast a shadow over this record, but the immunity mentioned above shows how vastly we have advanced over conditions of ten or fifteen years ago

A contract has been let for the removal of the fallen portion of the Quebec Bridge which now lies in a tangled mass upon the south shore of the river According to press reports the steel is to be severed for removal by means of a mechanical cutter, but we do not place much credence in the statement, for the reason that the obviously ideal method would be to use the oxy-hydrogen or oxy-acetylene flame, whose apparatus is so portable as to render it ideal for setting up in the many difficult positions which would be necessary

Comparative tests of consolidation and Mallet locomotives over mountain grades on the Southern Pacific Railway, under similar conditions of service, have shown all round economies in favor of the Mallet compound over the simple high-pressure locomotive of the standard type. The Mallet locomotive evaporated 7.81 per cent more water per pound of fuel, showed 14.04 per cent more ton miles per gallon of water used in the main cylinders, and 22.59 per cent more ton miles per pound of oil burned, and because of its greater size and power hauled 119.54 per cent more tonnage. The economy is due to the re-heating of the steam, the heating of the feed water, and compounding. The re-heater and feed water heater reduced the smokestack temperature of the gases from 735.5 degrees in the simple engine to 451.5 degrees in the Mallet type.

## ELECTRICITY.

Among the most important advantages of the "Pay-as-you-enter" car is the fact that these cars are safer to passengers getting on and off and fewer accidents occur from persons stealing rides Statistics have been compiled for the Chicago railroads which show that since "Pay-as-you-enter" cars were installed the number of accidents has been reduced 31 9 per cent.

A recent report of the American Telephone and Telegraph Company shows that at the end of 1909 the Bell companies owned 3,500,000 telephones, while 1,500,000 were owned by companies under contract agreements with the associated Bell companies. This is an increase of 600,000 telephones during the year The system comprises 10,250,000 miles of wire, 400,000 miles of which were added last year Half of the total mileage is underground

A test of Thomas A. Edison's storage battery car was recently made at West Orange, N J The car is 26 feet long and weighs 5 tons. It was fitted with two 7½-horse-power motors, and the operating cost is estimated at one cent a mile. During the test the car was operated at a speed of twenty miles per hour The motors are operated at 110 volts, and it is claimed that a run of 150 miles can be made without recharging the batteries

It has been reported that the Illinois Tunnel Company of Chicago is about to establish a system comprising 20,000 telephones which will be operated in competition with the present telephone system of the city The new system will make connections with long-distance independent lines. The Tunnel Company put in a system of automatic telephones ten years ago, but these are to be discarded and replaced with new and up-to-date apparatus

Metal filament lamps are now being used on ships and railroad cars. Such uses were considered impossible a few years ago owing to the frailty of the long filament required in these lamps, and it was supposed at the time that they could never be used anywhere but on a fixed support and hanging downward Now the filaments are so much stronger that in a recent railroad wreck the metal filament lamps in a car that was completely overturned were found to be in perfect condition and fit for further use in the regular service

At a recent meeting of the New York Electrical Society one of the speakers, lecturing on the subject of domestic electricity referred to a certain house that had been designed to be heated and lighted by electricity alone The house contains no chimneys stoves or coal storage room, and the saving in these requirements of the usual coal heating system was sufficient to pay for the entire electrical installation In regions where the cost of coal is high and water power is plentiful electric heating and lighting is no doubt more economical than coal heating

One of our large electric illuminating companies has found a new field for the consumption of electricity, namely, the Chinese laundry A Chinaman was induced to equip his shop with an electric washing machine and electric irons, and the photograph of this enterprising Oriental with his electrically equipped shop is being sent around among Chinese laundrymen, together with a letter written in Chinese calling attention to the advantages of modern methods in the laundry business It will be interesting to watch the success of this experiment

A carefully tabulated record of the cost of electric wagons and horse rigs used by the Commonwealth Edison Company of Chicago has just been published It shows conclusively that the electrically operated wagon is cheaper than the horse drawn vehicle and when we add to this advantage the fact that it makes a better appearance, is handier, and can cover ground in less time, enough has been said to show that the electrically operated wagon is far superior to the horse drawn vehicle and will undoubtedly displace it. Attention should also be called to the fact that the cost of the horse drawn rig is increasing each year, particularly because of the rise in the price of feed.

A thunderstorm observatory has been established in Spain by Senor G J de Guillen Garcia, in which atmospheric discharges, both local and distant, are detected graphically and acoustically A wireless telegraph instrument is used for this purpose, because each lightning discharge is accompanied by electromagnetic waves similar to those used in wireless telegraphy If there is a storm anywhere within a radius of 500 miles the observer is notified of the fact by the recording instrument. As all barometric depressions that pass over Western Europe come from the Atlantic Ocean, the new observatory gives meteorologists due warning of the approaching disturbance. By noting the intensity of the sounds produced in the receiver and observing whether they grow more distinct or less, it is possible to determine the approximate course of the storm.

## SCIENCE.

Lieut. Ernest H. Schackleton has announced that he will enter upon another Antarctic expedition The date of the expedition has not as yet been decided

The Brooklyn Public Library has published a little pamphlet on "Aeronautics or Aerial Navigation, which comprises a list of books and references to periodicals in the Brooklyn Public Library on the subject of aeronautics The list is fairly complete, and may be regarded as an excellent bibliography of a most timely subject.

A tyrannosaurus has been placed on exhibition in the Dinosaur Hall of the American Museum of Natural History This dinosaur measures 40 feet in length The jaws of the massive skull are four feet long and are armed with sharply pointed teeth Tyrannosaurus was probably the largest carnivorous animal that ever roamed the earth

The Scott expedition in search of the South Pole is now assured The British government has promised $100,000 toward the $200,000 which is the estimated expense A total of between $55 000 and $60,-000 has been raised by public subscription In all likelihood the expedition will start in July Capt Scott commanded the British Arctic expedition of 1900-1904 Shackleton was one of his lieutenants

Many attempts have been made to use old newspapers and other printed sheets in the manufacture of white paper, but the removal of the printers ink from the fiber has hitherto presented an insuperable difficulty In a process recently patented in Germany the paper pulp is treated with alkaline solutions of peroxides of the metals of the alkalis and alkaline earths, which so alter the greasy part of the ink that it ceases to bind the lampblack and other pigments, which are then easily separated from the fiber by emulsifying the pulp with gelatinous silica.

An international agreement for the prohibition of the use of saccharine has been instigated by the French government Favorable responses were received from Germany, Austria Hungary Belgium, Greece, Italy, the Netherlands, Portugal, Russia and Switzerland, and a meeting of delegates from these countries was held in Paris, under the presidency of the French minister of foreign affairs The commission closed its session on November 19th with the adoption of a formal prohibition of the use of saccharine in foods and beverages The French government will transmit this prohibition to the governments of the other countries for ratification

A recent German patent describes the preparation of a casting mass composed of slaked lime and water, with small quantities of alkali and a carbohydrate 100 parts of a stiff paste of well-slaked lime, containing approximately equal amounts of lime and water, are mixed with 1 or 2 parts of a carbohydrate free from water such as gum arabic, dextrin or sugar, and an equal quantity of a potash or soda salt which is decomposed by lime The mixture becomes as fluid as if a large quantity of water had been added to the lime, but soon solidifies and retains the form of any mold into which it is poured If about 2 parts of cellulose wood pulp or other fibrous material are added, good imitations of wood and ivory can be made

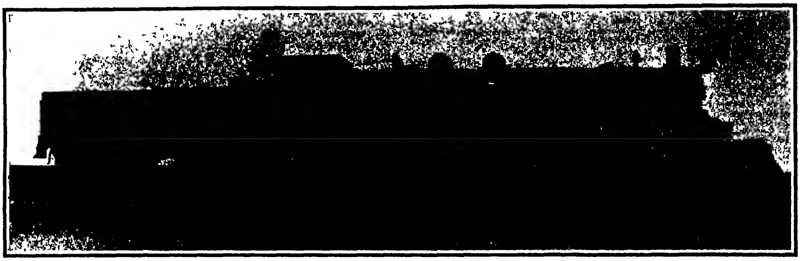
The investigation of the spectra of the planets, which was begun at Lowell Observatory in 1902, has been continued The result of recent work is given by V M Slipher in a bulletin just issued Slipher found a combination of dyes which renders the sensitiveness of the commercial dry plate fairly uniform into the red as far as to wave length 7 000 beyond which point it drops rapidly, but is sufficient at A to record faintly that line in the prismatic solar spectrum With the aid of this plate the spectra of Jupiter Saturn Uranus and Neptune have now been photographed with greater extension into the red than any previous photographic or visual observations and a number of lines and bands have been discovered

The beet is one of the most valuable of cultivated plants The red garden varieties furnish savory table vegetables, the large forage beets form an excellent food for cattle, and the sugar beet is one of the principal sources of sugar and alcohol The usefulness of this valuable root has now been increased by the production of an edible flour from sugar beets The desiccation of sliced sugar beets (Zuckerschnitzel) is already practised in Germany on a very extensive scale but the product is employed exclusively as fodder for cattle In Belgium, however, a meal is now made from dried beets which, according to a paper read before the recent chemical congress in London is entirely free from the distinctive flavor of the beet and is suitable for use in making cakes, puddings, and pastry As it contains about 65 per cent of sugar it can often be substituted, with advantage, for sugar, in somewhat larger quantities The processes of desiccation and grinding not only cost less than the extraction of sugar, but preserve all the sugar of the beet, part of which is rejected in the form of molasses, in the process of sugar making.

# A NEW ERA OF THE AMERICAN LOCOMOTIVE

## TWO REMARKABLE ENGINES

It is not stretching the point too far to say that the design of the locomotives herewith illustrated, one for passenger and the other for freight service, marks a new era in the development of the American steam locomotive. This is particularly true of the passenger locomotive, with which, by the introduction of the Mallet articulated piston, it has become possible to haul heavy fast passenger trains which with the present type of locomotive, it is necessary to run in two sections. Moreover, so powerful is this engine that it can haul over the heavy grades of the mountain divisions transcontinental trains which at present call for the assistance of an extra locomotive.

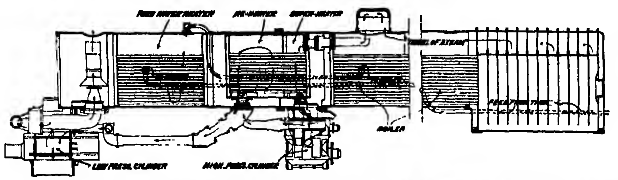


**Weight of engine and tender,** 305 tons. **Tractive force,** 25½ tons. **Heating surface,** 4,756 square feet. **Steam pressure,** 200 pounds. **Superheating and reheating surface,** 1,181 square feet. **Cylinders:** Two high pressure, 24 inches by 28 inches; two low pressure, 38 inches by 28 inches. **Driving wheels,** 73 inches.

**The most powerful passenger locomotive in existence.—A new type**

The Mallet articulated freight locomotive is already familiar, but the claim to distinction of the truly mammoth affair recently built for the Santa Fe Railroad is based on its great weight of 350 tons and its tractive force of 54 tons, both of which figures greatly exceed those for any previous freight locomotive. Both locomotives were built by the Baldwin Locomotive Works for the Atchison & Santa Fe Railroad.

The most important novelty, common to both engines, and the one which marks a distinctly new era in locomotive practice in this country, lies in the means which have been taken to transform the locomotive from one of the most wasteful into a reasonably economical power plant (if we may use the term). This has been done in both engines by utilizing the great length of boiler space afforded by the articulated system of construction. As will be seen from our sectional view, the boiler proper terminates above the high-pressure cylinders. The shell, however, is extended forward to the low-pressure cylinders, and within it are placed two nests of fire tubes, through both of which the hot gases pass on their way to the smokestack. The first of these is divided by a diaphragm into a superheater and a re-heater, the second forms the feed water heater.



In this boiler part of the heat in the furnace gases which is ordinarily lost through the smokestack, is utilized to superheat and reheat the steam on its way to the cylinders and to heat the feed water before it enters the boiler

**The new boiler which saves 25 per cent of fuel**

Now, in the ordinary locomotive the gases, still very hot, after emerging from the front end of the fire tube, pass out through the smokestack and waste an enormous amount of useful heat into the atmosphere. The Santa Fe locomotives return a large part of this heat to the boiler and engine. Referring to the diagram, it will be noticed that these heat recovery devices first serve to raise the temperature of the steam as it passes from the steam dome to the high pressure cylinder. Then the gases yield up still more of their heat to the exhaust steam as it passes from the high-pressure to the low-pressure cylinders, the heat so taken up by the steam serving in each case to raise the heat energy of the latter. Finally the gases pass through a large nest of tubes, around which the feed water is caused to circulate and is raised to the boiling point, as it travels from the tank on the tender to the boiler.

The advantages of this system are that not only is a much larger percentage of the heat energy of the fuel turned into useful work, but the super-heating and re-heating enable the well known economies of compounding to be realized to the fullest extent. As a consequence the coal consumption per ton mile has been reduced by approximately fifty per cent, ten per cent of which is estimated to be due to superheating and reheating, fifteen per cent to feed water heating, and twenty-five per cent to compounding. These figures are at present merely an estimate, but we see no reason why, with proper firing and intelligent handling of the throttle, these great economies should not be realized in actual service. The Santa Fe passenger locomotive embodies the first attempt to apply the articulated system to passenger service. The proportions are enormous, far exceeding any existing passenger locomotive either here or abroad. As far as cylinder and driving wheel arrangements are concerned, the engine is practically a combination of the

**Weight of engine and tender,** 350 tons. **Tractive force,** 54 tons. **Heating surface,** 6,621 square feet. **Steam pressure,** 220 pounds. **Superheating and reheating surface,** 1,745 square feet. **Cylinders:** Two high pressure, 26 inches by 34 inches; two low-pressure, 38 inches by 34 inches. This locomotive embodies superheating, reheating, feed-water heating, and compounding.

**The most powerful locomotive. Weight, 350 tons.**

**A NEW ERA OF THE AMERICAN LOCOMOTIVE.**

# PUTTING OLD NEPTUNE TO WORK

Twice each day millions of tons of shipping in New York Harbor are lifted to a height of over four feet and dropped the same distance by the tide This same work is done in every port to a greater or less degree. Many a man has enviously considered this enormous expenditure of power and racked his brains for a means of putting it to valuable service How ever, the work done by the tides is enormous only because of its vast extent and herein lies the delusion which many an inventor has failed to discover until he has devoted much thought and time on evolving a tide motor The work done in raising of the "Lusitania," for instance, which weighs 40,000 tons, represents an expenditure of energy of only sixteen horse-power, this being due to the fact that the tide acts very slowly, taking six hours to raise the vessel to a height of four feet.

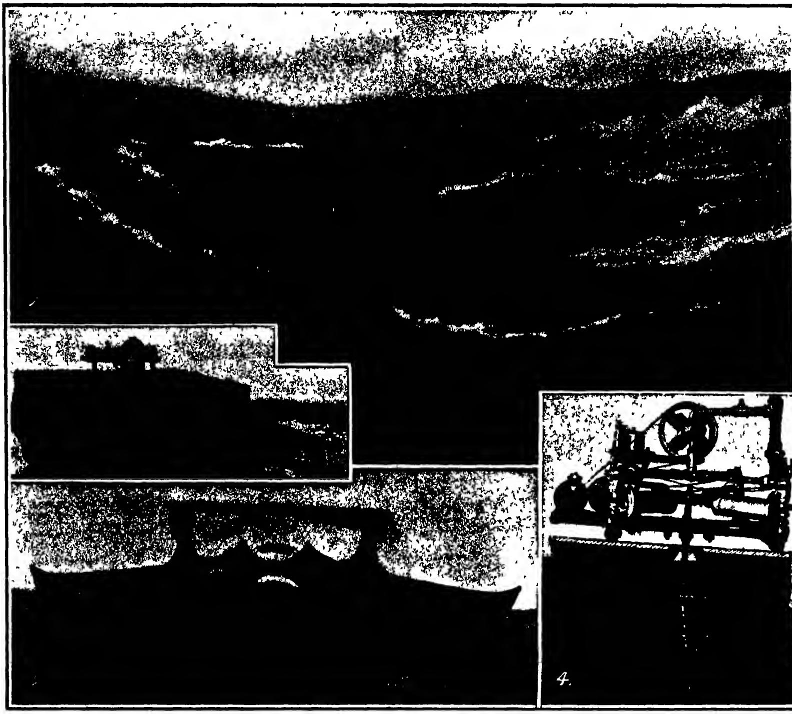
However, there is another form of energy displayed by the ocean which is far more powerful than that of the tide, and here there appears to be more opportunity for capturing a portion of this power and devoting it to practical use. The waves of the ocean are not so deliberate as the tides and the chief difficulty with which the inventor must contend is that in time of storm they develop entirely too much energy and are apt to wreck his machine.

In the accompanying engraving we illustrate some recent constructions which have been devised for the purpose of obtaining power from the waves. That shown in Fig. 1 consists of a large square float, on which the principal mechanism is mounted. Hinged to this float are four auxiliary floats and the rocking motion between the auxiliaries and the main float that is utilized to operate a series of pistons pumping air into a compressed air tank The compressed air tank and four pairs of cylinders are mounted on the main float The piston rods are connected at their outer ends to the four floats and when these floats are rocked by the waves they serve to reciprocate the pistons and pump the air This action takes place regardless of the direction in which the waves are traveling because the auxiliary floats extend in four directions.

An entirely different method of utilizing the force of the waves is shown in Fig 2. This consists of a large crib placed in the water and having one end open so that the waves will wash up over the floor of the crib as they do on an ocean beach At the back of the crib are a pair of curved deflecting walls before which is placed a triangular casing provided with a series of swinging doors or vanes. When the waves wash up the floor of the crib they close the vanes against the casing and divided by the prow of the casing are directed against the deflecting walls. The rear of the triangular casing is opened, permitting the water to flow through as the wave recedes and strike against the rear faces of the vanes opening them to the position shown in the illustration The vanes are geared to a series of piston rods which operate the cylinders to fill a compressed-air chamber. The latter, by means of a pair of air motors operates a dynamo and generates electricity which may be conveyed to any desired spot and utilized

Fig. 3 shows a construction similar to Fig. 1, making use of the rocking of two floats. The floats are hinged to each other and one carries a rack adapted to engage a pinion mounted on the other float. As the floats rock to and fro the pinion is rotated first in one direction and then the other, and this motion serves to pump air into a tank The air from the tank operates a pneumatic motor which in turn drives a dynamo and generates electricity In order to permit the floats to swing about in any direction without danger of fouling the anchor lines one of the floats is mounted on a swivel which is securely anchored By means of contact wheels engaging contact rings on the swivel the electricity generated is conveyed to a pair of cables which extend to the shore

The construction shown in Fig 4 depends for its operation on an entirely different principle It is well known that the wave disturbance of the ocean does not extend to any great depth and it is the relative motion of the surface water with respect to the water at a considerable depth that is made use of in this case to generate power A float is provided from the center of which projects a shaft fitted at its lower end with a set of radial fins When the float is rocked by the waves the shaft tends to remain vertical owing to these fins Mounted on the float are a series of cylinders provided with the usual pistons which are connected to an extension of the vertical shaft just referred to, and while the pistons remain virtually fixed the cylinders are reciprocated upon them by the rocking of the float The pistons serve to circulate oil through a rotary engine which in turn drives a dynamo and thus generates electricity When the wave motion becomes too violent an electrically-operated by pass permits a portion of the oil to circulate without passing through the motor and thus an excessive speed is prevented



Four novel methods of utilizing the power of the waves.

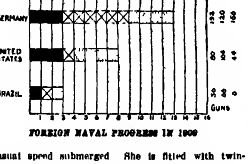
PUTTING OLD NEPTUNE TO WORK

## FOREIGN NAVAL PROGRESS IN 1909.

BY PERCIVAL A. HISLAM

During the year just closed considerable naval activity has been manifested abroad Not only have the principal naval powers adopted large programmes of new construction and made good progress with those already in existence, but the minor powers have shown in a practical manner how widespread a hold the Dreadnought fever has taken on the mind of the world

Great Britain during 1909 has finished the last of the trio of battleship-cruisers of the "Invincible" type, of the details of which readers of the SCIENTIFIC AMERICAN are already fully aware through the appearance of the "Inflexible" at the Hudson Fulton celebrations The three battleships of the 1906-7 programme—the "Bellerophon," "Temeraire" and "Superb"—have all been passed into service They are of 18,600 tons, 700 more than the "Dreadnought," but differ only in having sixteen 4 inch 31 pounders for their anti torpedo armament as compared with twenty-four 12 pounders The end of the year saw also the completion of the battleship "Vanguard," of the 1907-8 programme which was turned out by Vickers, Sons & Maxim in the record time for any ship since the "Dreadnought" herself, of 19 months The "St Vincent" and "Collingwood" completing the 1907 8 trio, will be commissioned this spring All are of 19,250 tons, and have ten 12 inch 50-caliber guns (the main armament of the others is 45 calibers) and twenty 4 inch rapid fire weapons. The thickness of the main belt is reduced to 9¾ inches in these ships compared with 11 inches in the earlier vessels, but a larger area of the hull is protected by thick armor Other vessels passed into service during the year include the unarmored cruiser "Boadicea," of 3 300 tons and 25 knots, designed to act as "mother ship" to the destroyer flotillas, a number of 33 knot destroyers—"Afridi" (which had to be accepted at 32 75 knots) "Crusader," "Amazon" "Saracen," "Maori," "Viking" and "Zulu" A new type of submarine has been completed This is the "D1" of 600 tons, which showed



*FOREIGN NAVAL PROGRESS IN 1909*

unusual speed submerged She is fitted with twin-screws, and has a steaming radius of 4,000 miles.

The vessels launched during the year are the battleship "Neptune," of 20 250 tons, with the same armament as the earlier Dreadnoughts, but so arranged that there is a broadside of the whole ten heavy guns, and the armored cruiser "Indefatigable," 19,000 tons, carrying the same battery as the "Invincibles," but longer, enabling a wider arc on either beam to be covered by the whole eight 12 inch guns A number of small cruisers and destroyers have also been launched

Three new battleships have been commenced They are the "Hercules," "Colossus," and "Orion," of the same displacement as the "Neptune," but with the five 12 inch gun turrets arranged axially The armored cruiser "Lion," also laid down will be of 26,000 tons and 28 to 29 knots, and will carry ten 12 inch guns

Germany has had a record year in naval construction She has completed her first two Dreadnoughts, the "Nassau" and "Westfalen," of 18,500 tons and armed with twelve 11 inch and twelve 5 9-inch guns. Both ships exceeded 20 5 knots on trial, although designed for 19 5 The armored cruiser "Bluecher" has been commissioned as flagship of the High Sea Fleet's cruiser squadron This vessel cannot rank with the British "Invincibles," but she is nevertheless a powerful ship, displacing 15,500 tons and steaming 24 5 knots on trial Her armament consists of twelve 8.2 inch and eight 5 9 inch guns, and her main belt is 8 inches thick The battleship "Rheinland," sister to the "Nassau" is now running her trials, and the "Posen" will follow this spring

Five large battleships have taken the water during the year Three of these are battleships—the "Ostfriesland" "Thuringen," and "Helgoland," each of 20,000 tons They are the first German ships to be armed with 12 inch guns Krupp's having built a 50-caliber weapon firing a 981 pound shell. Twelve of these guns will be carried as well as a similar number of 6.7 inch In armament at least, therefore, these ships will be greatly superior to any British ship yet launched. The armored cruiser "Von der Tann" has also been launched. She is of 18,700 tons and will steam 25 knots, her armament comprising ten 11-inch and a secondary battery, it is believed, of 5 9-inch guns. The cruiser "G," following toward the close of the year, is a sister ship

Two small cruisers, the "Kolberg" and "Mainz," have been completed. They are of 3,800 tons, carry fourteen 4 1 inch guns, and steamed 27 to 28 knots on trial The completion of destroyers continues a factor of naval strength in which Germany leads the world Her twelve vessels of the 1908 programme are in commission at a time when those of the British programme for the same year are only being launched

Three battleships have been laid down, similar to the "Helgoland," but equipped with turbines. They are the "Ersatz Frithjof," "Ersatz Hildebrand," and "Ersatz Heimdall" The armored cruiser "H," of the 1909 programme, was laid down in December, 1908, in advance of the orthodox date Two more small cruisers, twelve destroyers and some submarines have also been laid down

All the French battleships of the "Danton" class have now been launched They are of 18,400 tons and will carry four 12-inch and twelve 9 4-inch guns. Admiral Boue de LaPeyrere, the new Minister of Marine, has done much for the benefit of the naval service The next ships to be laid down, two of which will be started at once, will be of 23,400 tons and will carry twelve 12-inch and eighteen 5 5-inch guns

A start has been made in the re-creation of the Russian navy, and four battleships were laid down at the Baltic yards on June 16th last, where they will be built under the supervision of the British firm of John Brown & Co Their names are "Gangut," "Petropavlovsk," "Sevastopol" and "Poltava," and on a displacement of 23,000 tons they will carry twelve 12-inch and sixteen 4 7 The designed speed is 23 knots. The two Black Sea battleships "Andrei Pervosvanni" and "Imperator Pavel I" have been completed, as well as the small armored cruiser "Pallada," 7,900 tons. The former are 17,250-ton vessels, carrying four 12-inch twelve 8 inch and twenty 4 7 inch guns.

The progress of Japan is difficult to follow, owing to the contradictory reports that emanate from that country However, two battleships have been laid down—the "Kawachi" and "Settsu," of 20,800 tons, armed with twelve 12-inch, ten 6-inch and twelve 4 7 inch guns The "Satsuma," laid down in 1905, has been passed into service Displacing 19,250 tons, she carries four 12 inch, twelve 10-inch and twelve 6-inch guns Much difficulty is found in turning out ordnance fast enough to supply new ships, and the armored cruisers "Ibuki" and "Kurama," laid down in 1905, are still delayed by this cause Two new cruisers, the "Ibuki" and "B" have been laid down. On 18,650 tons they will carry six 12 inch and fourteen 6-inch guns, and steam 25 knots

Among the lesser powers Italy has laid down four large ships. The "Dante Alighieri" and "Cavour" (late "Leonardo da Vinci") will carry twelve 12 inch, and the "Michael Angelo" and "Galileo-Galilei," it is reported, eight 14 inch Austria has launched three battleships and proposes to build four 19,000-ton vessels as soon as financial difficulties have been overcome The first of the three Spanish ships, the "Espana," has been commenced, and will carry eight 12-inch guns on such a low displacement as 14,760 tons The Brazilian "Minas Geraes," with twelve 12-inch has been completed, the "Sao Paolo" is nearly ready for trials, and the "Rio de Janeiro" has recently been laid down The Argentine is going to have two battleships built, and Chile one A Chinese naval commission is touring Europe with the ultimate object of placing orders for three 15,000-ton ships; Turkey has sent Admiral Gamble back to England with instructions as to the ordering of two battleships, and Greece has allotted five million dollars for the purchase of an armored ship from an Italian firm.

## HOW AN AMATEUR MAY FIND HALLEY'S COMET.

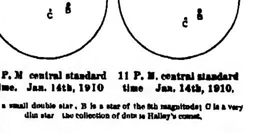
BY REV AUBL W ROBERTS.

Thinking it a laudable ambition to be the first amateur to find Halley's comet, I have been working with my 3½-inch telescope for several weeks trying to locate it. I have not learned as yet that I am the first, but being confident that I have succeeded in finding it, I have thought that other amateurs might like to know how it might be done Since the easy method here described may also be employed by amateurs in other simple studies of the heavens, I have gone somewhat into details. Despite the fact that some astronomical journals have said that it would be some time before the comet in question could be seen in a small telescope, I have the word of a prominent astronomer that it can now be seen in even a 3-inch—provided, of course, one knows where to direct his telescope.

So the first problem is to ascertain the position of the comet. There are very few amateurs who have telescopes mounted with circles. Hence we must adopt a plan that will enable us to find it without such aids. Of course it would be an easy task to locate it if one had all the equipment of an observatory, merely by setting the telescope in the proper right ascension and declination.

Now if we will turn to the recent files of the SCIENTIFIC AMERICAN, we may find the right ascension and declination given for every other day during January and February. The data for the intermediate days can be easily deduced by taking half the difference of any two alternate days and adding it to the reading of the previous day Next we need a good star atlas. Upton's is the one recommended in Young's Astronomy, and is the best for the average student. Such a star atlas should be one of the first books owned by an amateur Almost any good library can furnish you with such an atlas if one is not already at hand. Then with the ephemeris before you follow the course of the comet from day to day by tracing the right ascension and declination on the map. Note the day when the readings first come near to some prominent star This will be the time to put the method to trial. In order to know exactly how near the comet will be to the star, consult the Nautical Almanac or any other source accessible to find the R. A. and Dec. of the star Upton or other star atlases will give the data for some of the stars.

By this process I found that on the evening of November 30th the comet was to be near Aldebaran in Taurus, so I began in good season to make my trial The evening before I made four carefully constructed charts of the stars visible in my field of view I used my 45-power eyepiece, and this meant about 40 minutes or 42 minutes of arc, in the field. Upton on page 14 gives the R A of Aldebaran as 4 hr 30 min., and the Dec as + 16 degrees 19 min. The R. A. of the comet on this day was 4 hrs 30 min., and the Dec. + 15 degrees 56 min The R A is the same, and the Dec places it 23 min. south of Aldebaran This would bring it within the field of view of the telescope. One can estimate quite accurately the number of minutes of arc within the field of view of the telescope by sighting it upon some object whose size is known. The moon is suitable for the smaller powers it is 32



6 P. M central standard time. Jan. 14th, 1910 11 P. M. central standard time Jan. 14th, 1910.

A is a small double star, B is a star of the 8th magnitude; C is a very dim star the collection of dots is Halley's comet.

min of arc in diameter Epsilon Lyraee may be used for the higher powers. The two principal stars of this double (in reality a quadruple star) are 3 min apart. My 200-power presents a field of vision of about 6 or 7 min. Now if the polar axis of the telescope is pointed exactly to Polaris, it would be necessary only to make one map of the desired area and estimate the 23 min distance to the south I had my telescope, on this particular evening, directed from a second-story window and was not sure of my exact polar location, so I drew the four maps, hoping to be more certain of including the comet within the list. In making such observations and trying for a definite location north or south, east or west, one must bear in mind the fact that an astronomical telescope inverts the object. A little study with the moon, which can also be observed with the naked eye, will help to straighten out this matter Now after making these four maps on the evening of the 29th, I planned to observe carefully the next evening to see if I had any object in view not viewed the night before But the evening of the 29th was dimly illuminated by the coming rising of the moon, while the second evening was much darker, and I found many new stars in view While I had thus planned to locate the comet by a process of addition (and this would have been the more desirable as it would have enabled a more careful scrutiny) I decided to look for it the next evening by a process of elimination So on the evening of the 30th I carefully made four new maps of the same areas like those shown in the engraving and made about two weeks ago. Something like sixty or seventy stars appear in the cuts. After several evenings one star on the maps failed to appear again. I indicated this position by a small circle. So I concluded that this was the comet. I have since verified it by a sketch furnished me by a prominent astronomer. As it appeared in my telescope it had no such comet characteristics as a tail to enable one to readily recognize

(Continued on page 112.)

### THE LAKE WASHINGTON CANAL.

A public work of much importance, though not widely known, is the proposed canal connecting the tidal waters of Puget Sound with the fresh water lakes, Union and Washington, lying in or adjacent to the city of Seattle, Wash. The project is a very old one, though it has yet progressed no further than the acquirement of right-of-way, the formal adoption of a project by the War Department and its submission to Congress, and certain local measures now in progress for the raising of funds to aid the government in the work.

The canal is to be a joint enterprise, to the cost of which the government and the local community will ultimately contribute about equal shares. The local community has already acquired and delivered to the United States the right-of-way, costing about $250,000 It will excavate the channel at a cost of about $1,000,000 The railroads, street car companies and city will have to construct bridges and other crossings at their own expense, so that the entire local outlay will probably foot up about $2,500,000 The government will build the lock and controlling works and a power plant. It will also build the entrance works and take care of certain other features of the project and will maintain and operate free of toll the completed work The cost to the government will be about $2,500,000

Following are some of the benefits of this work which justify its construction and which also justify a division of the burden between the government and the local community

It will be of great value to the navy by giving an admirable fresh water waiting basin for vessels laid up in ordinary time of peace Puget Sound will always be an important naval rendezvous, and the Navy Yard is only 18 miles from the canal entrance.

It will give a much needed expansion to the harbor facilities of Elliot Bay The practically available frontage on the Bay does not exceed 5 miles, and a large part of this is in the hands of the railroads. The opening of the lakes will give fully ten times greater frontage than at present, and much of it better situated for public convenience It will make accessible extensive sites suitable for manufacturing establishments The areas at present available, where both rail and shipping facilities can be had, are extremely limited

The completion of the canal will give much needed anchorage grounds for shipping Many vessels are laid up during the winter, and owing to the excessive depth of water in Puget Sound, suitable anchorages are very scarce Not only will the lakes afford better anchorage grounds, but they are free from the destructive effects of marine life which is very active in the waters of the sound The hulls of vessels will suffer much less deterioration than in salt water Likewise subaqueous timber construction, which cannot be depended upon for more than a year in the sound unless the timber is "treated," is practically imperishable in fresh water The shallower depths also will be much less expensive for wharf construction and maintenance

The lakes are, of course, entirely free from tidal fluctuation, which on the sound has a mean range of 10 feet and an extreme range of 18 feet The fixed level will be a great gain in all shipping operations.

The foregoing advantages are of a general character, but there are others of a purely local character that are very important.

The cost of drayage in Seattle is large because of the extremely uneven topography of the city and the absence of good grades leading up from the present water front. The canal will flank the hills, distribute freight throughout the city and reduce the cost of drayage, it is estimated, by 25 to 50 cents a ton. This saving will in a few years equal the local contribution to the cost of the canal.

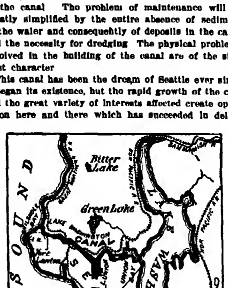
The lowering of Lake Washington to the level of Lake Union will drain all swamp areas around the shores of the lake, relieve the valley of Black and Duwamish rivers of the floods of Cedar River by turning the latter stream directly into the lake, and will make the whole run-off from the Lake Washington and Cedar River watersheds (580 square miles) available for power at the lock site. Drainage, flood protection, and accessibility to shipping will greatly enhance land values around the lakes. Lake Union will become virtually a great dock in the very heart of the city.

The removal of the natural barrier between the two lakes and the establishment of a connection with the sound will greatly enlarge the field of pleasure boating which already plays a large part in the life of the local community. Some fear is felt that the proposed changes will detract from the natural beauty of Lake Washington, but a careful analysis of the question shows that the effect will be imperceptible after a period of two or three years, and will result in improvement, so far as there will be any noticeable change.

The right-of-way for the canal is 300 feet wide. There will be a single lock with a large and small chamber. The large lock or chamber will be about 800 feet long by 80 feet wide and 26 feet deep and will take any vessel likely to visit Puget Sound for many years to come The little lock will be 150 feet long by 30 feet wide and 16 feet deep and will be used by small craft of all descriptions, the number of which is very large and rapidly increasing. Probably 90 per cent of transfers of vessels will be through this lock

The entire structure will rest on an excellent foundation of very hard, tenacious blue clay of great depth It will be built of reinforced concrete and steel and will embody the best features of modern lock construction The controlling works at the lock will consist of a power house by which the entire flow through the canal will be turned to use. The great reservoir formed by the lake gives complete control of the run-off and distributes the flow quite evenly throughout the year The revenue from this power will return about 14 per cent on the cost of the plant and will nearly pay for the future operation and maintenance of the canal The problem of maintenance will be greatly simplified by the entire absence of sediment in the water and consequently of deposits in the canal and the necessity for dredging The physical problems involved in the building of the canal are of the simplest character

This canal has been the dream of Seattle ever since it began its existence, but the rapid growth of the city and the great variety of interests affected create opposition here and there which has succeeded in delaying the work much longer than should have been the case It is now expected that the project will be completed within the next three or four years



This great salt water lake will form an excellent harbor for laying up naval vessels and will increase harbor frontage of Seattle

THE LAKE WASHINGTON CANAL

### The Boy's Endorsement.

Standing fifth among books most in demand during the week ending January 18, 1910, as reported by the Circulation Department of the New York Public Libraries, is "The Scientific American Boy," by A. Russell Bond This endorsement from the boys themselves counts for more than the many favorable reviews that this book has received Boys are not influenced by the criticisms that appear in magazines, nor to a great extent by advertisements The fact that they frequently call for a book at the library is evidence that they thoroughly appreciate that particular work "The Scientific American Boy" takes up the story of a group of boys who built tree huts, log cabins, caves, bridges water wheels, tents, tramping outfits, etc. A sequel to this book has just been published, entitled "The Scientific American Boy at School," which continues the story and tells how to make a variety of things, including dams, boats, gliding machines, sun dials, canoes, and many new devices for outdoor recreation

### The Current Supplement.

Some Curtis turbine driven units of 14,000 kilowatts capacity are in course of construction at Schenectady What 14,000 kilowatts means is shown in the Current Supplement by illustrating the amount of condensed water required, coal consumed, etc. The subject of marine propulsion by electric motors is presented. Lucien Fournier describes an automatic machine for registering letters A method is described for the handling, transporting and evaporating of liquid hydrogen for the inflation of balloons. Mr Albert Moyer, the well-known authority on concrete, presents a paper on the possibilities of the uses of mineral oils mixed with concrete. The treatment of disease by injecting into the blood the serum, or watery part, of the blood of an animal that has been made immune to that disease is popularly discussed by Dr Fritz Meyer Dr V Grafe contributes an excellent article on the miniature art of Nature and Science Suggestions are made for observing Halley's comet. Dr H A Gins writes on the optical method of studying immunity to bacterial disease Many of our readers have no doubt wondered how an explorer can really prove that he reached the Pole, in view of the recent Copenhagen decision The method of examining an explorer's notes and ascertaining whether or not he reached the Pole is excellently presented by Professor J Hammon Smith

## Correspondence.

### WHY BAND SAWS BREAK

To the Editor of the SCIENTIFIC AMERICAN

Mr H Miner of Lumberton, Miss, has inserted an article in your valuable paper, the SCIENTIFIC AMERICAN of November 13th, 1909 concerning the causes of breaking of springs He also relates the breaking of bandsaws, which is a very important point to overcome, as it is a well known fact to all who use bandsaws that a saw after running a few hours becomes longer in the back edge on account of the back pressure from the saw guide which gradually brings the tension more and more toward the teeth or sawing edge

If any little cracks exist by reason of improper finishing they will certainly increase and the flaw will break If the manufacturers of bandsaws would study this matter they would soon find out that the fault lies in the careless way of making the steel and preparing it for a saw

Manufacturers who have won reputations for making bandsaws in smaller sizes as from ¼ inch to ½ inch, are looking for too great a profit and forgot to make use of the same skill exerted in making bandsaws for exhibition

By an average approximate estimate a ¾ inch bandsaw will not run long enough to wear for one-half dozen filings before it is broken in so many places that it is impossible to make any more use of it.

Chicago H JOHANSEN

### A CURIOUS PHENOMENON.

To the Editor of the SCIENTIFIC AMERICAN

While driving along the shore of Canandaigua Lake, in the State of New York, on Tuesday, January 4th, I observed a curious natural phenomenon

The temperature of the air was six degrees above zero, a light northwest wind blowing and the bright sun of the afternoon occasionally obscured by the presence of large and low hanging cumulus clouds.

The surface of the lake was covered by vapor caused by the difference in temperature between the cold air and the comparatively warm water This vapor visible in the form of a slowly rising, dense, white mist gathered in spots in masses rising higher than the surrounding mist As these masses of vapor reached a height of some twenty feet they appeared to take on a rotary motion and formed themselves into columns slowly rising until their apexes met the low lying clouds, where they spread out in a funnel shape exactly as do water spouts The columns varied from a foot to possibly ten feet in diameter, some of them ascending in a straight line and others bent into fantastic curves by the action of the wind I saw a great number of these mist whirls during a drive of some two hours, covering a distance of ten miles along the lake shore, and as they formed and drifted slowly across the water illuminated by the rays of the setting sun, they were a beautiful and to me a unique spectacle

Can you tell me if similar phenomena are often observed? JAMES S. LEE.

Boston

Speaking before the Royal Society in London on the subject of magnetic storms Mr E W Maunder superintendent of the Solar Department of the Royal Observatory, Greenwich said that magnetic disturbances were in some way connected with the rotation of the sun upon its axis It was clear that, besides sending us light and heat the sun sent some kind of influence which came only from certain portions of the surface and came along closely restricted lines They found there was a tendency for magnetic disturbances to take place when a sun spot had got to a definite portion on the sun's disk If they took it that the influence that came from the sun and struck the earth came from the center of the sun spot, they would be able to calculate how long it had taken place, and, assuming that, they found it would take about twenty-six hours to come from the sun, a distance of 93,000,000 miles, to the earth

# A GREAT OPEN-AIR TELESCOPE

BY PROF. S. A. MITCHELL

COLUMBIA UNIVERSITY

A giant telescope has been erected in Germany having for its main purpose the making of astronomy popular through exhibitions to the public of the heavenly bodies. The United States has repeatedly followed Germany in her advances along scientific lines and here would be a splendid opportunity to emulate her by the erection of a great public telescope (say) in New York city.

A contrast of this new German telescope at Treptow (near Berlin) with the highest development of American manufacture proves of the greatest interest. In the Yerkes telescope (see SCIENTIFIC AMERICAN, December 25th, 1909) we have a great instrument given over to exact research, handled by a corps of expert astronomers, leaders in their special lines of work. Prof. E. E. Barnard is there with his keen eye for the measurement of the positions of comets, star clusters, etc., for the depicting of slight planetary details, or with the help of the photographic plate for the portrayal of Mars on a large scale. The greatest living authority on double stars, Prof. S. W. Burnham, spends two nights each week with the great 40-inch refractor. The director, Prof. E. B. Frost, takes care of the spectroscopic side of astronomy by photographing the spectra of stars for the determining of their motions in the line of sight, and by day time the telescope is made use of to learn of interesting phenomena about the sun. This great telescope is a model of engineering perfection with its great tube and massive parts, rising floor and rotating dome. It is mounted in what is known as the equatorial form.

But how different is the Treptow telescope! Erected with other purposes in view, it is not necessary to have expert scientists to keep the telescope employed almost every hour during the day and night. Constructed under a different plan, it is unnecessary to have a great elevating floor inside of a huge rotating dome, for in fact the dome is done away with and the telescope is used in the open air! This then brings something radically new in the old science of astronomy, something entirely different in the construction of a great telescope. And this new form of instrument has many points in its favor that make it a most interesting telescope.

The director of the Treptow Observatory, Dr. F. S. Archenhold, by his radical ideas came into opposition with the German scientists who ridiculed the idea of placing in the open air with no protection from the wind a great tube 68 9/10 feet in length, seven feet longer than the Yerkes telescope (62 feet). But undaunted, Dr. Archenhold persevered and finally succeeded in collecting sufficient funds for the erection of the largest telescope in the world. And this, too, in scientific Germany!

The front page illustration shows the Treptow telescope. The old equatorial form of mounting was departed from, for this requires that the eye-end of the telescope be raised through a vertical distance approximately half the length of the telescope tube in viewing a star overhead and one near the horizon. This necessitated a very expensive elevating floor run by electric motors (SCIENTIFIC AMERICAN, December 25th, 1909). By swinging the telescope tube in a great fork and employing suitable counterpoises Dr. Archenhold was able to have the eye-piece near the center of motion, and run the telescope tube upward into the air. The details of this will be readily seen by referring to the illustration. This eliminated the rising floor and saved many thousands of dollars. The low forked mounting with its heavy movable parts placed on a solid concrete foundation insured a stable instrument, and as the whole construction had no great height it became possible to house the telescope by turning the long telescope tube into a horizontal position and pulling over it a cheap portable house. By using the telescope in the open air it became possible to entirely eliminate the great dome, and thereby save again more thousands of dollars. The result of these plans were that Dr. Archenhold was able to build the completed instrument for the modest sum of $62,500. Of this sum $11,500 was spent for the lens, which was made of the celebrated Jena glass ground by the old-established firm of Steinheil, in Munich. The lens is 27 inches in diameter, and is an excellent one.

The radical departure from old-established forms in eliminating the dome has many points in its favor besides the mere saving of money, and also many drawbacks. As is well known to astronomers, the temperature of the night air is continually falling (especially in the early part of the night), and it is impossible to have the air in the interior of the dome at the same temperature as the outside air. This causes the heated air to pour out through the slit of the dome, and also produces currents of air in the interior of the telescope tube itself. All of this makes "bad seeing," and a distortion of the telescopic image—the bane of the existence of the professional astronomer.

View taken under the mounting, showing the electric motors for driving the telescope.

A GREAT OPEN-AIR TELESCOPE.

Dr. Archenhold's plan of doing without a dome eliminates most of the effects of air currents, for there is no "dome effect," as astronomers call it, and the air in the telescope tube quickly takes the temperature of that outside. Here, then, is a decided advantage. But unfortunately the telescope being in the open air makes it the sport of every passing wind, and even a slight wind is apt to set up a vibration in the telescope, especially so when the tube is so long as in the Archenhold telescope, which is supported not in the middle, as in the ordinary telescope, but entirely at one end. Though the vibrations may be small and imperceptible to the eye, still when the telescope is pointed at a fixed star the immense magnifying power of the long telescope would make even the slightest tremors readily visible and would spoil the use of the instrument for accurate work. It would seem that for the important researches of the exact astronomer the open-air telescope would be a failure, but for public exhibitions only it is another story. The absence of dome and rising floor eliminates a great amount of the expense, and the modest amount of the popular subscriptions can be all put into the construction of a telescope, thus obtaining a much larger instrument. The telescope is raised and a star located by means of a 6½-horse-power electric motor. In order to keep the telescope pointed correctly at the celestial object, it is necessary to drive the telescope to make it move from east to west, otherwise owing to the earth's rotation the object would quickly move from the field of the telescope. In the Treptow telescope both observer and instrument must be moved, and the details of how this is done by a ½ horse-power motor regulated by clockwork can be seen in the smaller illustration.

## The Cost of Our Navy.

IT COSTS A GOOD DEAL OF MONEY TO RUN A NAVY

The actual expense of running the navy of the United States for the past fiscal year amounted to $43,790,000. In this sum is included everything, from the pay of enlisted men to the repairs and equippage of vessels. And the vessels include the tugs and receiving ships as well as the battleships.

The battleship "Connecticut," flagship of the Atlantic fleet, may be taken as an example of the cost of keeping a vessel of that type in service. The pay of officers and enlisted men attached to this vessel with the other expenses amounted to more than $790,000 during the fiscal year just passed. The Atlantic fleet in that period included sixteen first-class war vessels, viz., six of the "Connecticut" type, five of the "Georgia" class, and the others ranging from 13,000 tons to 11,500 tons. The average cost of keeping a vessel of the "Georgia" class in commission, not including repairs, is $677,500 a year. The classes below the "Georgia" require expenditures ranging from $532,000 to $604,000. While the figures will vary for the same vessels in different years, the cost changes very little from year to year for the same class. $10,521,000 was the total cost for running the sixteen ships of the Atlantic fleet for the past year. There were twenty-three first-class battleships in commission last year, and the total cost of keeping them in service, exclusive of repairs, was $13,035,000, making an average cost for running them $592,084. On all these ships the repairs amounted to only $100,496.

It might seem strange, but it is a fact nevertheless, that it costs more to maintain a cruiser than it does a battleship. There were ten armored cruisers in commission last year, the total cost of running amounting to $7,150,600, or an average per ship of $715,060.

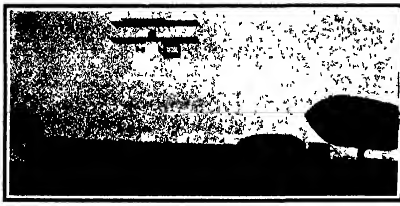
It would seem at the present time that there is to be no limit to the increased size of future battleships, and naturally there will be an increased cost of running expenses. For instance, the latest battleships to be placed in commission, the "Michigan" and the "South Carolina," each require a crew of 51 officers and 818 men. These vessels are of 16,000 tons displacement. The next that will be ready for service are the "Delaware" and "North Dakota," each of 20,000 tons displacement. Each of these fighting crafts will require 55 officers and 876 men. Then will come the "Florida" and "Utah," each of a normal displacement of 21,825 tons. These monsters of the sea will have in their respective complements 60 officers and 954 men. But we have not reached the latest vessels yet. The contracts have already been let for the "Arkansas" and "Wyoming." Remember the "Oregon" of Spanish American war fame? Well, that is only half a battleship besides these. They displace 26,000 tons each, with a crew of 1,036 men, and 85 officers to command.

The Philadelphia Rapid Transit Company reports that on certain of its lines in that city since the introduction of "pay-as-you-enter" street cars, the number of accidents to persons has decreased 74 per cent. This remarkable change is attributed to the arrangement of closed doors and steps, making it impossible for passengers to get on or off when the cars are moving.

# AMERICA'S FIRST AVIATION MEET AT LOS ANGELES

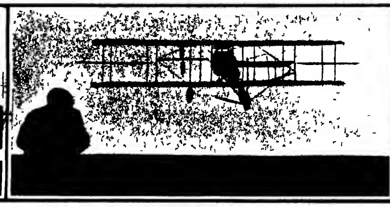
## DETAILED ACCOUNT OF THE FLIGHTS MADE BY THE AMERICAN AND FRENCH AVIATORS

The first aviation meeting to be held in this country opened at Los Angeles, Cal., on the 10th instant. Louis Paulhan, the record-breaking French aviator, was present with two Farman biplanes and two Bleriot monoplanes. America was represented by Glenn Curtiss, C. F. Willard, and C. K. Hamilton, all of whom flew Curtiss biplanes. The field that served as an aerodrome was located a few miles from Los Angeles. It was not an ideal place for flying since it was not level. One end of the field was at a considerably higher elevation than the other and the machines were, therefore, obliged to fly quite high in order to pursue a level course. A hexagonal course of 1.61 miles was used. Only a few short flights were made by Messrs Curtiss and Willard the first day. Messrs Beachy and Knabenshue, in their dirigible balloons, flew 200 feet above the grand stand against a wind of 10 to 12 miles an hour. Paulhan made his initial flight of 8½ minutes at this time, covering an estimated distance of 4¾ miles. In the second flight he remained aloft 10 minutes. His third flight lasted 29 minutes. He



**The two Farman biplanes flying in front of the grand stand.**

The Knabenshue and Beachy dirigibles are seen at the right



**Chas. F. Willard flying in the Curtiss biplane of the Aeronautic Society.**

Mr. Willard won the prize for alighting upon a square having 20-foot sides.

**Mme. and Mons. Louis Paulhan.**

The daring French aviator and his wife hold the record for cross-country flying

**The Bleriot monoplane in flight as seen from a balloon.**

**Making a turn**

These two views of the Bleriot monoplane give a good idea of its equally bird like appearance when viewed from above or below. Paulhan flew this machine without difficulty, but his inexperienced assistants met with accidents and broke both machines

**Paulhan making his record-breaking high-flight in the Farman biplane. He reached an official height of 4,165 feet**

This machine is the most improved type of biplane produced abroad. A single vertical rudder is now fitted between the surfaces of the tail in place of the twin rudders used heretofore. The hinged wing tips for stability are set into the rear edges of the planes. Note also the combined wheels and skids for running on the ground and alighting. One blade of the propeller can be seen below the revolving-cylinder motor at the rear

**AEROPLANES AND DIRIGIBLES AT AMERICA'S FIRST AVIATION MEET AT LOS ANGELES, CAL.**

sides dashing at the grand stand and just clearing the heads of the spectators, he flew out of sight over the neighboring ranches

On the second day the first flights were made by Paulhan, who took out his new Farman biplane and drove it thrice around the course in a stiff wind, said to be of 18 miles an hour velocity, which was blowing from the sea Next for variety he mounted one of the tiny Bleriot monoplanes, with which Miscarol had been attempting to get off the ground He had no difficulty in flying it in the wind that was blowing Although it bobbed up and down and was tossed about like a small boat on an angry sea Paulhan flew about the field and several times swept past the grand stand, performing various maneuvers and rising to an estimated height of 200 feet The spectators gave a sigh of relief when he finally landed across the field from the stand He was soon out again with his Farman biplane, in which he quickly disappeared from view far to the north Shortly after he reappeared over the trees of a nearby ranch, and frequently charged at the grand stand, turning aside just in time to clear the spectators or else to sweep over their heads This flight of about 8¾ miles lasted 21 minutes and 12 seconds It was the fourth flight he had made on the second day of the meeting After Paulhan's flights, Mr Curtiss brought out his Rheims racer, which is fitted with an 8-cylinder water-cooled motor of 50 horse-power Mr Fanciulli climbed on board with Mr Curtiss, and the machine shot into the air for its speed test with a passenger After describing a wide circle in front of the grand stand Curtiss flew around the course at a speed figured out by Lieut Paul Beck, of the Army Signal Corps—one of the judges—at over forty miles an hour Paulhan immediately started a flight At the same time Messrs Willard and Hamilton started on their Curtiss biplanes in front of the grand stand Curtiss followed them a few moments after with Mr Clifford Harmon as a passenger All four machines were flying at the same time a spectacle well worth seeing Paulhan landed a few minutes later, took on one of his mechanics as a passenger and twice circled the course as readily as he had done alone

Curtiss established a new starting record and also a record for landing but Willard beat Curtiss in the latter respect Curtiss started from a marked square of 400 square feet flew once around the field in something over two minutes and landed exactly on the square from which he started He broke his own record for starting by getting off the ground in 6 2/5 seconds after a run of but 98 feet Paulhan required 12½ seconds time and a run of over 100 feet

The great event of the third day was Paulhan's successful attempt at breaking the world's record for altitude The existing record had been made only six days before by Hubert Latham at Mourmelon, France, with his Antoinette monoplane, and was 3,444 feet Paulhan started in front of the grand stand, and heading north, he went steadily upward in circles until he was nearly a mile high So high did he fly that to the eyes of the onlookers the machine appeared the merest speck in the sky After ascending some 46 minutes, he pointed his biplane once more toward the earth, and came down at a much greater angle and in about one-sixth the time (7½ minutes) The registering barometer on his machine registered 1 535 meters or just over 5,000 feet, so that Paulhan had apparently beaten Latham's record by some 1 500 feet He was given a great ovation upon landing The total length of the flight was 53 minutes 46 1/5 seconds Paulhan's height, as measured from the ground, was officially determined at 4,165 feet.

The fourth day Paulhan gave a good demonstration of the weight-carrying ability of his new Farman machine which is much smaller and weighs 225 pounds less than the regular Farman biplanes, by taking up his two assistants Maisson and Miscarol, and circling several times around the course with them. Curtiss circled the course ten times in 24 minutes 54 2/5 seconds. Paulhan tried to beat this time and failed by five seconds only Previously, he made three laps in 8 16 1/5 carrying his wife as a passenger After circling the field he alighted readily in the marked-off square from which he started In another flight of 7 minutes' duration he carried Mrs Ferris as a passenger. He again resorted to his sensational methods, flying low over the grand stand, making sharp turns, etc Hamilton, Paulhan, Curtiss and Willard qualified in three-lap flights for all events The first named made a flight with his vertical rudder locked, in order to show that this rudder does not have to be used in connection with the balancing planes, as is done by the Wright brothers when they warp the planes of their machine to correct its transverse equilibrium This combined operation of the equilibrium-maintaining device with the vertical rudder is one of the strongest claims in the Wright patent. Where plane warping is employed, it is necessary, in order to prevent the slewing around of the machine, when the plane is warped to a greater angle. With balancing planes like those used by Curtiss, the resistance inserted at one end of the machine is as great as at the other, the consequence being that the vertical rudder does not necessarily have to be used. This flight with the rudder fastened demonstrated very well the difference between the two systems. Mr Willard again flew once around the course and landed in a measured square, thereby winning a prize of $250 Paulhan was presented with a $500 silver cup by enthusiastic citizens of San Diego The next day he made a cross-country flight of some 16 miles to San Pedro and back, circling above the revenue cutters in the harbor and being greeted with cheers by the inhabitants Paulhan also made 6 circuits of the course with his assistant in 18¼ minutes, and afterward flew twice around it alone in the Bleriot monoplane His fastest lap in the latter machine was done in 2 48, which equals a speed of 34 14 miles an hour Curtiss made the fastest lap of the course in 2 12—a speed of 43 45 miles per hour Subsequent to a race with Beachy, Knabenshue made a lap in his dirigible in 5·10 2/5—a rate of 18 4 miles per hour Hamilton tried for the slow lap prize and succeeded in making one circuit of the course in 3 36 2/5—a speed of 26 78 miles an hour The time of Willard's slowest lap was 3 11 1/5 Hamilton made a 12 minute flight for altitude, reaching a height of 530½ feet.

But very little flying was done on the sixth day of the meeting, owing to wind and rain The field was wet and muddy, but notwithstanding this, all the aviators got off the ground without much difficulty and made a few short flights. Paulhan attempted to beat Curtiss' ten lap record, but he was unsuccessful Willard and Hamilton also made an attempt at this record, the latter covering the 16 1 miles in 30 34 3/5 or at an average speed of 31 7 miles an hour Miscarol, Paulhan's assistant, made a brief exhibition flight with a Bleriot monoplane In landing, the machine tipped to one side, causing the wing to strike the ground and break off The accident was blamed upon the substitution for wing warping of the movable ends of the tail, which normally move together and act as the horizontal rudder By moving these ends of the tail in opposite directions, the transverse equilibrium can be maintained fairly well under ordinary conditions, although this method is not so positive as that of warping the wings themselves.

Sunday January 16th, but few flights were made, as the weather still remained inclement. The following day, however, Paulhan attempted to break Farman's record of 4 hours and 17 minutes. After remaining aloft 1 hour, 58 minutes, 27 2/5 seconds, during which time he covered 75 6 miles, Paulhan was obliged to descend on account of a leak in the gasoline tank. He therefore did not come within 2¼ hours of equaling Farman's record Hamilton also flew during some of the time that Paulhan was making his endurance flight. He kept at a lower level and made 11 circuits of the course, but was obliged to stop on account of motor trouble Curtiss lowered his time for ten laps to 23 minutes, 43 2/5 seconds (40.71 miles an hour) His fastest lap was three seconds slower than his best previous circuit. Paulhan covered ten laps in 25 5 1/5. Beachy made one lap in his dirigible in 4·57 4/5 (19 46 miles an hour) This was the fastest lap scored by any dirigible during the meet. The Gill-Dosch biplane, which is very much like the Curtiss, and which was constructed by two gentlemen from Baltimore, Md., made several attempts to get off the ground, but was only successful in making a few short jumps. Mr. Clifford Harmon made a short flight alone in his new Curtiss machine.

Tuesday, January 18th, is noteworthy for the long cross-country flight of Mons. Paulhan, who flew to "Lucky" Baldwin's ranch and back, a distance of about 47½ miles, in 1 hour, 2 minutes, 42 4/5 seconds. In the course of this flight he rose to a height of 2,130 feet, according to the registering barometer carried in the biplane Most of the time he was at a height of between 1,000 and 2,000 feet. During the return journey, which was made in about 23 minutes, Paulhan had to fight against a rather strong westerly wind, and yet he is said to have required only about three minutes more returning than he consumed in flying to the ranch Probably at the elevation at which he was traveling he did not encounter as strong a wind as was blowing near the earth.

January 19th was given up to the making of a number of flights with passengers. The weather was perfect save for a puffy wind in the early afternoon, which later died out altogether About 2·30 P. M Paulhan started on a cross-country flight with his wife as a passenger After circling once around the field he left the course and headed directly toward the ocean. He flew at a height of some 500 feet to Redondo Beach In the course of his flight he passed over several other neighboring seaside resorts. He returned safely after 33¾ minutes, having covered over 20 miles across country without difficulty This flight was twice as long as that made by Orville Wright at Fort Meyer last summer in the speed test for the government It is the longest cross-country flight ever made with a passenger, although it was not by any means as hazardous as the one made by Mr Wright. Other flights were made with Mrs. C F Bishop, Lieut. Paul Beck, W R. Hearst, and a reporter for a New York newspaper For the second time Lieut Beck tried dropping dummy bombs upon a measured square on the ground While he did not succeed in hitting the mark, he came very close to it, and showed the possibility of dynamiting a warship or a town in this way Paulhan's last flight was made with Mr Harmon as a passenger It was a cross-country flight of 8 to 10 miles lasting about 20 minutes. Hamilton made three attempts at high flying, rising to heights of 455, 300, and 700 feet, respectively The Gill Dosch biplane was finally made to fly and was driven once around the field by Hillary Beachy In descending, however, it was badly damaged Curtiss made two laps, but was unsuccessful in breaking his speed record

The last day of the meet, January 20th, Curtiss made the longest flight he has ever accomplished Starting at 3·25 P M, Paulhan had made but two or three laps, when Curtiss went aloft about half a lap behind him Mounted on his Rheims racer, Curtiss steadily gained upon Paulhan, and after making three laps passed him in front of the grand stand, his small biplane flying directly above the larger French machine. This was the first real race the spectators had witnessed, and Curtiss received great applause He continued to fly around the course until he had covered 30 laps (48 3 miles), his time being 1 16 39 Paulhan made 35 circuits of the course (56.35 miles) in 1 34·34 The average speeds of Curtiss and Paulhan were respectively 37 8 and 35 77 miles an hour Hamilton made a flight to Moneta, about 7 miles from the aviation field. He rose to a height of several hundred feet and disappeared from view upon the horizon. Upon his return the crankshaft of his motor broke when he was nearly back, and he succeeded in gliding down to the field and alighting without mishap A feature of the last day was a parade showing the evolution of locomotion. The parade opened with an old-time "prairie schooner" and ended with the aeroplanes.

Prof. J. S. Zerbe's multiplane. This machine is of the following plane type.

A NOVEL AMERICAN AEROPLANE AT THE LOS ANGELES MEET

### The Boston Aeronautic Show.

The first Aeronautic Show to be held in America as a separate affair will open in the Mechanics Building, Boston, Mass., the evening of February 23rd. This show will be held under the auspices of the Aero Club of New England, and a number of men well known in the aeronautical world stand sponsors for it. Besides numerous models of aeroplanes, there will be exhibited a number of full-sized representative machines. A duplicate of the United States government's only dirigible balloon will also be on view. Inventors and experimenters having anything to exhibit should communicate at once with the manager of the show, Mr Chester I. Campbell, 5 Park Square, Boston, Mass.

# Patent Department

## TOOL FOR CUTTING STAY BOLTS.

Stay bolts in locomotive boilers usually break near the inner side of the outside boiler sheet. When the broken bolt is in position behind the frame of the locomotive it is necessary to drill the bolt on the firebox and drop it out of the way, after which a hole is bored

TOOL FOR CUTTING STAY BOLTS.

through the stub in the outside sheet and the part of the bolt remaining is cut out with a round nose chisel This is difficult to do, and it sometimes happens that the sheet is grooved in the operation, and trouble is caused thereby With a view to overcoming this difficulty the tool illustrated in the accompanying engraving has been invented. It consists of a cutting member arranged to move in a sheath which can be fitted into the hole drilled in the bolt and serve as a guide for the cutter which is then operated to cut out the bolt. The body of the tool, which is of hexagonal form, is indicated at *A* Projecting from the body *A* is a blade *B* formed with a bead *C* at its lower edge The sheath above referred to is indicated at *D* and is formed with a central bore to fit the bead *C* and a slot to receive the flat portion of the blade as indicated in Fig 2 The sheath *D* is reduced at *E* to form a centering guide. The bolt to be removed is first drilled out, as indicated in Figs 3 and 4, to the diameter of the part *E* of the sheath The portion *E* is then fitted into the bore, after which the cutting tool is operated to drive the end *F* of the blade into the bolt and cut it out as indicated in Fig 1 After the bolt has been cut at three or four points it may easily be knocked out. Mr William Smith of Peshtigo, Wis., has secured a patent on this new cutting tool.

## UTILIZING CENTRIFUGAL FORCE PRACTICALLY

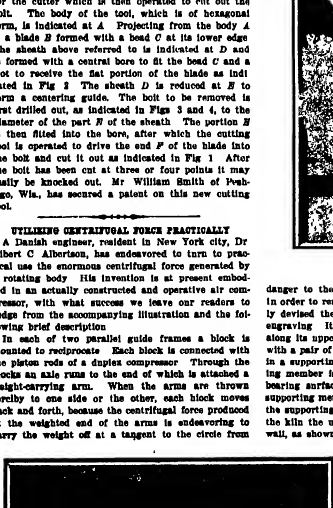
A Danish engineer, resident in New York city, Dr Albert C Albertson, has endeavored to turn to practical use the enormous centrifugal force generated by a rotating body His invention is at present embodied in an actually constructed and operative air compressor, with what success we leave our readers to judge from the accompanying illustration and the following brief description

In each of two parallel guide frames a block is mounted to reciprocate Each block is connected with the piston rods of a duplex compressor Through the blocks an axle runs to the end of which is attached a weight-carrying arm. When the arms are thrown forcibly to one side or the other, each block moves back and forth, because the centrifugal force produced at the weighted end of the arms is endeavoring to carry the weight off at a tangent to the circle from its own center. But the center of each circle is the axle in the respective block. Hence the blocks move outward in their guide frames as the arms are thrown out. The angle bearings, center, arm weight are all therefore constantly changing position so long as the arm is being turned fast enough Each centrifugal arm in its flight does not describe a circle, but rather an ellipsoidal curve due to the shifting of the block

The two guide frames, as has been stated, are placed parallel to each other, each having a block, arm, weight, etc. The blocks are held in opposite positions so that the arms will balance each other and so that the two blocks will always reciprocate in opposite directions.

The means employed to hold the centrifugal arms in position, and yet allow them to follow their respective "pulls," consists of a shaft between the guide frames with two crank arms, each of which has a pin extending into a slot cut in each arm The crank shaft is driven by a small motor As the cranks turn, the centrifugal arms are turned by the pins which project in the arm-slots. The greater the speed of the crank, the greater the power of the centrifugal arms Because there is no connection between the centrifugal arms and the cranks, the reciprocating action of the blocks is caused entirely by centrifugal force

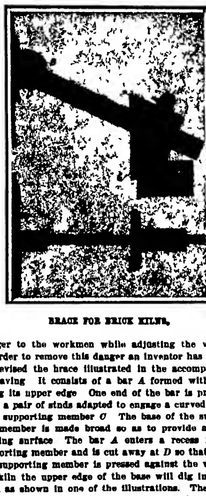
It is a curious though easily comprehensible fact the amount of centrifugal force developed was so great in the machine illustrated that it was necessary to cut away part of the material of each arm and to reduce the weight so that the pistons would not hammer against the cylinder heads.



CENTRIFUGAL MACHINE.

## BRACE FOR BRICK KILNS.

During the process of baking bricks the kilns expand and contract, and if the sides are not braced after they have contracted they are apt to topple over if the kiln should expand again Hitherto it has been the custom to brace the sides of a kiln with timbers and wedges which work involves considerable



BRACE FOR BRICK KILNS.

danger to the workmen while adjusting the wedges In order to remove this danger an inventor has recently devised the brace illustrated in the accompanying engraving It consists of a bar *A* formed with teeth along its upper edge One end of the bar is provided with a pair of studs adapted to engage a curved slot *B* in a supporting member *C* The base of the supporting member is made broad so as to provide a large bearing surface The bar *A* enters a recess in the supporting member and is cut away at *D* so that when the supporting member is pressed against the wall of the kiln the upper edge of the base will dig into the wall, as shown in one of the illustrations. The teeth on the bar *A* are adapted to be engaged by a pawl *E* which is fulcrumed in a member *F* that is supported on a timber disposed along the side of the kiln The member *F* is held in place by teeth *G*, which dig into the wood The pawl *E* is provided with a thumb piece *H* by which it may be lifted out of engagement with the ratchet teeth in the bar In using this brace the workman thrusts the supporting member *C* against the side of the kiln and places the member *F* in position on the timber Then pressing against the kiln with his foot he takes up the slack between the two members *C* and *F* by engagement of the pawl *E* with the ratchet teeth on the bar *A* Mr Anatole Perusse (care of J McLean, 245 East Strand, Rondout, N Y) has just received a patent on this improved brace for brick kilns.

## BUTCHERS' SCALE PAN.

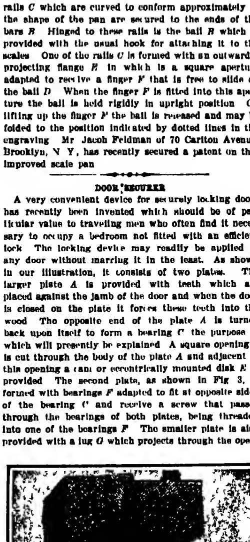
It is customary for butchers to weigh meat in large scale pans that are usually provided with a rigid bail which is also of large dimensions, and the fact that the bail is rigidly attached to the pan makes it inconvenient to stow away the pan when it is not in use The accompanying engraving illustrates an improved form of butcher's scale pan in which the bail is so mounted that it may be folded down against the pan when it is

BUTCHERS' SCALE PAN WITH FOLDING BAIL.

not in use, but whenever desired may be locked rigidly in an upright position The bail is not directly connected with the pan, but to a pair of rails which serve to distribute the strain In our illustration we have lettered the pan proper *A*. Riveted to the pan at the bottom are a pair of diametrically disposed straps *B* which cross each other at right angles and are bent up at the ends against the sides of the pan The two rails *C* which are curved to conform approximately to the shape of the pan are secured to the ends of the bars *B* Hinged to these rails is the bail *D* which is provided with the usual hook for attaching it to the scales One of the rails *C* is formed with an outwardly projecting flange *E* in which is a square aperture adapted to receive a finger *F* that is free to slide on the bail *D* When the finger *F* is fitted into this aperture the bail is held rigidly in upright position On lifting up the finger *F* the bail is released and may be folded to the position indicated by dotted lines in the engraving Mr Jacob Feldman of 70 Carlton Avenue, Brooklyn, N Y, has recently secured a patent on this improved scale pan

## DOOR SECURER

A very convenient device for securely locking doors has recently been invented which should be of particular value to traveling men who often find it necessary to occupy a bedroom not fitted with an efficient lock The locking device may readily be applied to any door without marring it in the least. As shown in our illustration, it consists of two plates. The larger plate *A* is provided with teeth which are placed against the jamb of the door and when the door is closed on the plate it forces these teeth into the wood The opposite end of the plate *A* is turned back upon itself to form a bearing *C* the purpose of which will presently be explained A square opening *D* is cut through the body of the plate *A* and adjacent to this opening a cam or eccentrically mounted disk *E* is provided The second plate, as shown in Fig 3, is formed with bearings *F* adapted to fit at opposite sides of the bearing *C* and receive a screw that passes through the bearings of both plates, being threaded into one of the bearings *F* The smaller plate is also provided with a lug *G* which projects through the open

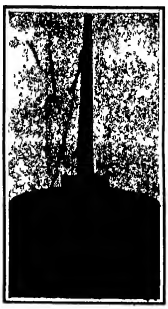


SIMPLE DEVICE FOR SECURING DOORS.

ing *D* in the plate *A*. The lug *G* is recessed to receive the cam *E*, and the latter is turned to press the step *H* against the door and thus lock it shut. In order to allow for the movement of the smaller plate as the cam *E* is turned the bearing *C* of the larger plate is elongated as shown in the drawing. The inventor of this door securer is Mr. Charles W. Lent of Tingley, Iowa.

### AN OIL CAN

The oil can illustrated in the accompanying engraving belongs to the class embodying a flexible bottom which is operable to cause a flow of oil. The construction here shown, however, is arranged to provide a considerably greater flow of oil than is obtainable in cans of the conventional construction. This result is secured by providing three diaphragms in the can, one of which serves as the bottom of the can, while the other two are connected at the center by a nipple. In this manner an oil chamber separate from the main portion of the can is formed. In the accompanying engraving the can is shown at *A* with the usual nozzle *B* threaded into the upper end. Fitted into the lower end of the can is a retaining ring *C* which has extending flanges at the upper and lower ends and is also bent outwardly at the lower end to fit against a shoulder formed in the can body. The dished diaphragms *D* and *E* bear against the flanges of the retaining ring. The two diaphragms *D* and *E* are connected at the center by the nipple *G*. The diaphragm or bottom *F* is soldered fast to the can body. An oil chamber is thus formed between diaphragms *F* and *E*. In operation when the bottom of the can is pressed inward it drives the oil from the oil chamber with greater pressure than would be the case if the entire can body formed a single oil vessel. At the same time

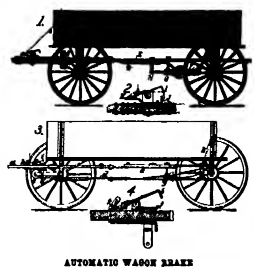


TRIPLE-BOTTOMED OIL CAN.

the other two diaphragms yield as well, thus effecting a large discharge of oil. Mr. Frederick G. Svetlik of Cadott, Wis., has recently secured a patent on this improved oil can.

### AUTOMATIC WAGON BRAKE.

Two patents have recently been issued on the subject of wagon brakes, describing a form of brake for use on carriages and wagons, that will be automatically applied when the horse is checked or presses back against the load when going down hill. The brake may also be applied by hand and can be thrown out of automatic operation whenever it is desired to back the vehicle. In order to take off the strain upon the mechanism when traveling around curves or over rough roads, a flexible connection is made between the tongue and the brake mechanism. In Fig. 1 the tongue is indicated at *A*. It is provided with a crowned roller *B* mounted on a vertical axis which bears against a crown roller *C* mounted on a horizontal axis. The roller *C* is carried between two arms of a brake reach *D* which are disposed at each side of the main reach *E* and are free to slide longitudinally in the hounds. The brake reach *D* is connected at the rear end to a lever *F* which is connected by chains to the brake beam *G*. The latter carries the brake shoes that bear against the rear wheels of the vehicle. The brake beam is connected by a spring to a post *H* carried by the main reach *E*. It will be evident that when the tongue is pressed backward or when the vehicle rides forward on the tongue the brake reach will throw the lever *F* backward, drawing the brake shoes into engagement with the rear wheels. A hand lever extends upward from the lever *F* to permit of operating the brakes manually. In order to throw the automatic mechanism out of operation the tongue *A* is locked to the hounds by means of a simple mechanism. It consists of a lever *I* with a downwardly projecting flange adapted to engage a flanged piece *J* carried by the tongue. The lever *I* is mounted in brackets secured to the hounds and is normally spring-pressed out of engagement with the piece *J*. A cord running from the lever *I* to within convenient reach of the driver may be drawn upward to throw the lever *I*, whereupon a latch *K* will engage a stop piece serving to hold the lever in set position. With the crosspiece *J* set as shown in Fig. 1 it is possible to lock the brakes against the



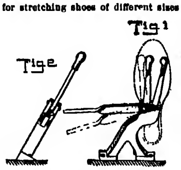
AUTOMATIC WAGON BRAKE.

wheels, while if the piece *J* is set with the flange at the opposite side, as shown in Fig. 2, it serves merely to lock the tongue to the hounds in such position that it cannot set the brakes.

The second construction referred to is similar to that shown in Fig. 1, and corresponding parts are referred to by the same, but lower-case, letters. The tongue *a* is connected to the brake reach *d* by means of a chain *b* which passes over a pulley *c*. The brake reach *d* is connected to a lever *f* which in turn is connected by means of chains to the brake beam *g*. The brake beam is connected by a link to the main reach *e*, and is held in inoperative position by a spring attached to the brake reach *d*. The hand lever for operating the brake is shown at *h*. A locking device similar to that shown in Fig. 2 is indicated in Fig. 4 comprising a lever *i* mounted on the hounds, a lug *j* mounted on the tongue and a latch *k*. The inventor of these wagon brakes is Mr. Eben G. Dolan of Starksboro, Vt.

### ODDITIES IN INVENTIONS

IMPROVED SHOE STRETCHER.—The shoe stretcher illustrated herewith is so arranged that it may be adjusted for stretching shoes of different sizes and shapes, and for applying the pressure at any point desired so as to stretch the shoes to a comfortable fit. The stretcher is provided with a stationary base, formed with an arm at its upper end, which terminates in a knob. Fulcrumed in the base is a bell-crank lever, one arm of which is also provided with a knob, mating that of the fixed arm. By depressing the bell-crank lever, the knobs will be forced apart, stretching the shoe at the points of contact. These knobs are removable, and are provided at one side rounded and the other projecting. Each knob also has a square tapered opening adapted to fit the arms of the shoe stretcher. The knobs may readily be applied, either with the projecting portion bearing against the shoe, or with the rounded portion, as desired.



IMPROVED SHOE STRETCHER.

ROCKING ATTACHMENT FOR ROCKING CHAIRS.—An inventor has recently procured a patent on a device for rocking chairs, without placing the feet on the floor. The particular advantage of this scheme is that a slight movement of the feet will cause the chair to rock. Fulcrumed to the rockers are a pair of levers fitted with rollers at one end to engage the floor, at the opposite end connected by means of links to a pair of bell-crank levers forming a sort of a treadle, on which the operator's feet are supported. By pressing this treadle downward, pressure will be brought to bear on the rollers, causing the chair to rock. When desired, the mechanism may be thrown out of operation by folding the treadle up against one of the cross pieces of the chair.

ROCKING CHAIR ATTACHMENT.

### Doctoring Oriental Rugs.

Of the hundreds of thousands of dollars worth of Oriental rugs brought into the United States annually, many of them are what is known to the profession as "washed rugs." This means that brightly colored Oriental rugs are sometimes washed with a solution of chloride of lime, a treatment which partly bleaches the colors and imparts a soft appearance to the rug. The chemical treatment is a process of washing which produces the effect of age and a peculiar sheen to the surface, which is pointed out by many dealers as a proof of superior quality. The fact is, however, that the process of washing invariably weakens and in some instances destroys the materials of the rug. The progressive effect of the chemical treatment of the rug is this. The chlorine gas contained in the chloride of lime attracts oxygen and moisture from the air, by which muriatic acid is formed. This eats away the vitals of the fabric. Sooner or later the wool and cotton in the rug become brittle, and thus weaken the warp and deteriorate the wool. When this deterioration is complete, the pile of the rug may be swept away by the ordinary process of sweeping, and the warp, which is the foundation of the rug, becomes so weak that holes appear here and there, and soon the rug is worthless.

It not seldom happens that a Persian rug is too glaring in some bright hue, perhaps red, and is not salable. An unscrupulous dealer will subject the rug to the series of washings in chemically prepared water. In this way he turns out a rug possessing a soft antique sheen that is truly captivating, and finds a ready purchaser for the doctored floor covering.

### A New Comet Discovered in South Africa.

A new comet visible to the naked eye was discovered at Johannesburg on January 16th by Innes, in right ascension 19 hours, 50 minutes, 28 seconds and declination minus 23 degrees, 59 minutes 24 seconds.

At the time of its discovery the comet had an hourly motion in right ascension of plus 41 seconds of time and declination of plus 6 minutes 4 seconds of arc.

The comet discovered is brighter than Venus. At Lick Observatory it was easily seen with the naked eye at noon about four degrees east of the sun and one-half degree north of it, moving northeast.

For a few nights the comet was a brilliant object in the clear southwestern sky just after sunset.

Readers of the SCIENTIFIC AMERICAN will hardly confuse this comet with Halley's, which has been the object of constant study since September 11th, when it was sighted. The South African body is one of the two or three comets which are usually discovered every year.

---

Dr. Joseph E. Pogue who is in charge of the Division of Mineralogy in the U. S. National Museum, has recently described in the Smithsonian Miscellaneous Collections a remarkable specimen of pyrite studded with crystals of gold and partly covered with plates of galena from the Snettisham district near Juneau, southeast Alaska. The pyrite is in the usual form of a cube, but what is very remarkable is that there are on it more than one hundred and thirty well-defined crystals of metallic gold. These are also in the cubical system and from one-third to one-half buried in the pyrite, never more, and seem to have no definite relation to the crystallization of the pyrite. Similarly, crystals of galena and chalcopyrite are found on the pyrite. The structure and relation of the galena to the pyrite is of considerable scientific interest and is described in technical detail by the author. This very unusual occurrence of these minerals in crystallographic juxtaposition is described by Dr. Pogue as follows: "The pyrite, when its present size was nearly attained, sustained a deposition of crystallized gold upon its surface followed by the precipitation of a small amount of chalcopyrite which, in turn, was succeeded by the formation of the galena. A further slight accretion of pyrite completed the development of the specimen."

---

Failure of a fly-wheel, says Power and the Engineer, usually begins by the starting of a minute crack on the under surface of the rim at the point of greatest stress, viz, near the ends of the arms adjacent to the rim joint. The cracks gradually deepen until failure occurs, with all its disastrous consequences. These minute cracks are visible to an experienced eye, and careful inspection will aid materially in the prevention of fly-wheel explosions.

## RECENTLY PATENTED INVENTIONS.

### Electrical Devices.

STORAGE BATTERY.—P. M. Marko, New York, N. Y. In this case the invention refers to improvements in storage batteries, and more particularly to means whereby the strength of the battery may readily be ascertained without the aid of outside instruments, attachments, or connections. The electric meter is constructed to specially adapt it to the battery and need have a range of only the capacity of the battery.

ELECTRICALLY-OPERATED HAMMER.—L. Paulero, Petersburg, Va. The present invention relates to hammers of the type referred to in a former patent granted to Mr. Paulero. It contemplates means for maintaining various parts cooled while in action under conditions wherein such parts are usually heated. It also provides means for improving the adjustment of the stroke of the hammer.

ELECTRICAL-FUSE BLOCK.—A. A. Moffitt and G. E. Andrews, Providence, R. I. In this case the invention relates to fuse blocks and fuses to be used in connection therewith, the more particular purpose being to so adjust the fuses relatively to the fuse block, as to prevent the insertion in a particular block of a fuse built for greater amperage than one intended to be inserted in said block.

KEYBOARD-OPERATING MECHANISM.—H. Krugman and H. Harta, 12 Cyril Mansions, Battersea Park, London, England. This invention relates to a system of type-setting by wireless means which can be attached to or worked in combination with linotype machines or those of similar construction and relates particularly to means for the operation of type-setting apparatus of the type in which parts are synchronously moved in the transmitting and receiving machines so that when a contact is made in the former a corresponding one is made in the receiving machines.

### Of Interest to Farmers.

PLOW.—J. Colomá, Caracas, Venezuela. The purpose of the inventor is to provide an improvement upon the old Arabian plow still widely used in the Spanish republics, whereby to render the said type of plow more efficacious without complicating its construction and to better adapt it for use in mountainous districts.

PRUNING IMPLEMENT.—A. H. Bastian, Bellwood, Neb. In use an operator takes hold of the pole with one hand and the runner sleeve with the other, which will enable him to hook the fixed blade upon a limb or branch to be removed whereupon a downward sliding movement of the sleeve will rock a lever downward and forcibly rock a blade so that its convex cutting edge will impinge upon the limb and sever it. Means provide for restoring the blades for renewed service.

COTTON CHECKER AND CULTIVATOR.—R. Hamilton, Gouldbusk, Texas. An object here is to provide a device by means of which the width of the hills or rows may be adjusted to suit the requirements of various grades of soil. Further, to provide means by which the plows of the cultivator may be simultaneously raised or lowered, and when so may be kept in their adjusted positions. Mr. Hamilton has invented another checker and cultivator for use in simultaneously raising and lowering a plurality of plows in a cultivator and means for simultaneously turning a plurality of disk cutters.

JOINTER ATTACHMENT FOR PLOWS.—P. S. Stokes, Shreve, Ohio. Means are provided for detachably connecting a single or double pointed jointer blade directly upon the standard of the plow share and near to the mold board forming an upward extension thereof which will cut off vines, shear cut sod, and turn such cut material as well as loose soil into the furrow formed by the progressive movement of the board and plow share.

COTTON HARVESTER.—D. H. Mays, Benoit, Miss. The harvester is adapted for gathering cotton from the maturing plants and for separating the same from foreign substances which are gathered therewith. In gathering cotton, it effects the operation without injuring the plants and leaves them in the same condition as before the cotton is gathered.

BALING-PRESS.—J. O. Kelberry, Upper Sandusky, Ohio. Among the principal objects in view are to provide a mechanism for pressing hay or like substances by successive steps and with maximum pressure, a mechanism wherein the return of pressure mechanism to the receiving position is rapid, means whereby the material being handled by the device is fed in unison with the pressure mechanism, and means whereby the pressure mechanism is positively returned to its initial position.

### Of General Interest.

MOISTENER.—J. H. Bordeaux, Joliet, Ill. In the present patent the invention is an improvement for moisteners for labels, envelopes, stamps and other gummed surfaces, and it is designed as either a desk or pocket article, in which capacity it is intended to be both sanitary and leak-proof.

LUBRICATOR FOR CABLES.—W. F. Scamehorn, Republic, Mich. In the traverse of cables employed for the draft of cars and general haulage purposes in mines and other places, it frequently occurs that cables are unduly worn from frictional contact with each other if they cross or with supporting means such as pulleys or the like. The device automatically coats a running cable with a lubricant and removes any excess, thus preventing injurious wear or rusting of a wire cable.

HORSESHOE.—R. C. Marrs, Trenton, N. J. The object here is to provide a shoe arranged to securely hold the calks in position without danger of the calks becoming accidentally loose while the shoe is in use to allow of conveniently removing the calks for sharpening, the renewal or exchange of calks for summer or winter wear and without requiring the removal of the shoe from the hoof.

MANDOLIN.—A. Manarillo, New York, N. Y. In this instance the tone of the instrument and its clear and distinct notes are improved by constructing the body of two cases, an inner and outer respectively, both cases being substantially the same shape and spaced from each other at both the sides and bottom, the inner case preferably having a number of openings in the bottom for the escape of the sound waves.

SNOW MELTING APPARATUS.—M. Johanson, New York, N. Y. This invention pertains to improvements in means for melting and disposing of snow accumulating on sidewalks and in streets, and the aim is to so construct the apparatus that the water resulting from the melting may be delivered to a higher elevation in the building than the snow receiver.

CARRIER.—J. P. H. Henry, Jr., St. Paul, Minn. This device is especially adapted for removing litter and the like from stables, the carrier consisting of a fixed portion which is adapted to take the place of the ordinary gutter at the rear of the stalls, and an elevator proper for receiving the litter from the fixed or horizontal portion and depositing it in a pile remote from the stalls.

FEED BAG.—H. B. Drobin, A. Drobin, and L. Drobin, New York, N. Y. It is the purpose of this invention to provide a feed bag in which the sides at all times remain stretched out or are non-collapsible in a vertical direction, a bail to suspend the bag from the animal's head, and springs compressed by the weight of the feed in the bag and varying the effective length of the bail.

YARN.—W. P. Wood, Pawtucket, R. I. This inventor provides a spun or twisted yarn adapted to be used in the manufacture of fabrics having irregular uneven surfaces, and more particularly provides a yarn spun from cotton or other fiber which when used as a filling will give to the fabric substantially the rough and uneven appearance characteristic of rough pongee fabrics.

DEVICE FOR SPINNING GLASS.—I. Wirakopf, Murchenstern, Austria-Hungary. The advantages in this case consist in arranging an optional number of means beside one another whereby the output which is possible for one workman is considerably increased. The most important is the use of a fusing point, whereby a small harbor is provided for the fusing glass by which the temperature can be gradually increased up to the melting point of the glass, and dropping of the latter and breaking of the filament caused thereby are prevented.

METALLIC MOLD.—H. G. Lasseller, New York, N. Y. The purpose of this inventor is to provide a mold for use in building houses and other structures of concrete or other cementitious and like plastic material, the mold being made in sections capable of being set up and removably connected with each other to allow the use of the mold for a great variety of work.

REINFORCED PARTITION WALL.—E. Flagg, New York, N. Y. The invention concerns itself especially with the mounting and supporting the wire and with means for rendering the wire taut before the plaster or cement is applied. Partition walls when constructed upon studding have a considerable thickness and in this way considerable floor space is lost. The wall in this invention can be made very thin and will give a consequent saving in floor space.

PRESSURE-REGULATOR.—J. Kenlon, New York, N. Y. The intention here is to produce a regulator to be connected with the hose, and which operates to prevent the bursting of the hose and injury to the men. It will enable the stream passing to the hose to be reduced and regulated when desired or will enable the full force of the stream to flow unobstructed through the hose.

BOTTLE LABEL.—I. Levi, Anniston, Ala. As the liquid is poured from the bottle a ring will sink following the liquid, this sinking movement being permitted by prongs. Should, however, an attempt be made to refill the bottle, the prongs will prevent the upward movement of the ring, which consequently will be submerged beneath the fluid, thus indicating that the bottle has been partially refilled.

VALVE FOR IRRIGATING SYSTEMS.—J. Lang, Clearmont, Wyo. The purpose of the valve is to control delivery of water into the laterals. It is so constructed that the valve proper may be raised so as to allow a restricted, or free flow of water into a lateral. The valve is not only for vertical adjustment, which is afforded by means of a screw shaft, but also to be swung laterally when it is required to uncover the water inlet or opening to the fullest extent.

SYRINGE.—T. R. McNerthney, Tacoma, Wash. By the action of gravity and the production of a partial vacuum the combined douche and syringe effect a thorough but gentle embrocation of diseased walls of the "os" and parts with a medicinal liquid and then remove the medicament together with pus and other secretions, by a free liquid irrigation of the diseased tissue. It is also serviceable for use in the ear, nose or other diseased cavities of the body.

### Hardware and Tools.

FILTER.—H. P. Strahl, Cleveland, Ohio. An object of the inventor is to provide a durable filter for filtering air or other fluids with which, filter material of different kinds can be employed, in which the filter material is securely held in place by adjustable caps and in which the casing has a head forming a lock nut for one of the caps.

SPECIFIC GRAVITY BALANCE.—B. R. Jolly, Raleigh, N. C. In carrying out this invention Mr. Jolly provides a scale by which the object to be assayed may be first balanced in air and then in water by moving the weight farther from the pivot or center of the balance beam. The quality or fineness of the substance may then be determined immediately by means of a scale which is rotated until it reaches a stop, when the reading may be taken directly.

PLIERS.—C. R. Cotaino, Crescent City, Cal. The principal objects in this case are to provide a construction for pliers wherein the clamping jaws are pivotally mounted to operate in substantially parallel lines in closing, to provide a simple and efficient form of construction, and to provide a construction wherein the parts are readily separable for repair or substitution.

SQUARE OR GAGING DEVICE.—J. T. Blair, Tulsa, Okla. In this case the invention pertains to a device the purpose of which is to facilitate the laying out of carpenters' work or similar work, and the purpose is to provide a device by means of which the length and angle of the rafters, hips and valleys of roofs may be readily ascertained.

NUT LOCK.—J. McIlwain, Okawville, Ill. In the present patent the invention refers to certain improvements in nut locks and more particularly to that type of nut lock in which a retainer of wire or the like engages within grooves, openings or apertures in the nut to prevent the latter from turning.

KEY FASTENER.—I. O. Shain, Smithfield, W. Va. The invention relates to key fasteners, and more particularly to such as are adapted to prevent the accidental displacement of a key positioned in a lock, and each of which in general includes a stop and means for operatively disposing the stop in a predetermined position to bar the key hole and prevent the withdrawal of the key.

FASTENER FOR STORM WINDOWS AND WINDOW SCREENS.—J. Michaelson, Peterson, Minn. The aim of this inventor is the provision of a device which is convenient to apply to a window casement and is adapted for reliably holding a storm window or a screen in place within a window casement, on the inner side thereof, and permit the extra window or screen to be quickly detached from the casement.

FLUE-CUTTER.—W. H. Damon, New York, N. Y. The invention belongs to that class of a cutter in which a mandrel to fit within the flue is provided with an eccentrically arranged tool carrying shaft having a limited relative rotary movement to project and withdraw the tool. It is a cutter in which the mandrel has a yoke head and a shaft provided with a thumb controlled member rigid with the shaft and arranged between the arms of the head.

### Heating and Lighting.

LAMP.—C. M. Daniels, Paris, Ill. Mr. Daniels supports the mixing tube and burner directly from the fuel supply pipe or vaporizing chamber in such a way that the mixing tube and burner may be readily removed. The burner itself is removable from the mixing tube, the construction of the burner and the means for supporting it, constituting another feature of his invention.

SAFETY ATTACHMENT FOR GAS LIGHTING BURNERS.—H. E. Campbell, New Haven, Conn. The principal objects in view are to provide an attachment wherein the heat of the flame maintains the flow of gas, to provide an operating medium which will not become frozen or lost by evaporation and to provide a construction simple and efficient in its operation.

FURNACE-GRATE OPERATING MECHANISM.—H. Bevan, Burlington, N. J. The grate is depressible from the bottom of the fire-box to empty the latter and provide space for the insertion of a gas ring, as in the spring and fall when heating the house for a portion of the day. The invention further contemplates locking of the grate when raised and the locking of the grate shaking means when the grate is depressed, to provide a fixed rest on which the gas ring may be slid to position of use.

WATER TUBE BOILER.—W. S. Lucas, Marshall, Ill. The intention of the inventor is to provide a boiler designed for use in generating steam for motive power or for heating buildings by steam or hot water and arranged to provide an exceedingly large heating surface and to use the fuel economically and to the fullest advantage.

AUTOMATIC CUT-OFF FOR GAS MAINS.—C. E. Lahmers, New Philadelphia, Ohio. This device is for use in preventing explosions or accidents caused by the changes in the pressure in gas mains. One object of the invention is to provide a device which will automatically shut off the flow of gas from the mains when the pressure therein becomes too low, thereby preventing the accidents which otherwise might occur.

GAS-FIXTURE.—A. Jarmolowsky, New York, N. Y. In view in this present invention is a construction in which the lighter, as it is revolved moves the controlling valve to turn on the gas to the several lights or burners in successive order, the flow of gas to each burner starting at the time the burner is reached by the lighter. It is an improvement on a former patent granted to Mr. Jarmolowsky.

### Household Utilities.

AUTOMATIC DAMPER OPERATING DEVICE.—F. H. Muller, Lansdale, Pa. This invention provides novel means for simultaneously operating the dampers of a cooking stove or range at a predetermined time, so as to start a smoldering fire therein into free burning condition and means for sounding an alarm at the same time the dampers in the range are adjusted to produce free draft therein.

JAR HOLDER.—H. F. Peterson, Keokuk, Iowa. The aim of the invention is to provide a device serviceable in construction and inexpensive to manufacture which can be easily mounted on a receptacle such as a pan or the like, and which serves to hold a number of preserve jars in place while the latter are being filled.

BRACKET FOR SUPPORTING CURTAIN POLES AND SHADE ROLLERS.—A. S. Dunson, Springfield, Ill. Brackets have been constructed which support poles and rollers so that they combine two functions, but they have been made of so many parts and otherwise constructed in such manner as to be comparatively expensive and unsatisfactory. In the present bracket all the parts save the hook which serves to support one end of the roller and the rod and spring are formed integrally or in one piece and may, therefore be produced at minimum cost.

WASHING MACHINE ATTACHMENT FOR STATIONARY WASHTUBS.—W. Walton, Jr., New York, N. Y. The invention is an attachment for tubs, and is designed to provide a washing apparatus embodying a washing cylinder which may be readily applied to and operated in stationary tubs of various sizes, and the cylinder easily removed when desired to use the tub in the usual manner.

MATTING ROLLER.—A. F. Shannon, Columbus, Ohio. Matting is comparatively stiff and has a slippery surface difficult to roll upon a bar or spindle. This inventor has attained success with the present invention, that is to say with a bar or spindle formed of spring material and having a lengthwise slot in which a block is inserted and permanently held and serves to separate the halves of the spindle more widely than normally.

AWNING FIXTURE.—J. Sullivan, New York, N. Y. A purpose here is to provide a fixture, one which will obviate the necessity of attaching the upper portion of the fixture to the window casement and one wherein a person standing on the window sill or operating from a suitable point in the room, may conveniently and almost in a moment place the awning in position for immediate use.

WASHING MACHINE CYLINDER.—J. H. Golter, Greensboro, N. C. In this machine the brace ribs operate to strengthen and support the perforated jet ribs. The latter tend to cause the water to pass through the perforations with force as the cylinder revolves in the water, thereby making it easier to mix the washing ingredients with the water and facilitating such mixing and the washing process.

### Machines and Mechanical Devices.

LOG HANDLING DEVICE.—J. H. Stoner, Smithsburg, Md. The object here is to provide a device for use in connection with saw mill carriages and the like which can be arranged adjacent to the carriage to assist in turning the log by means of a cant hook or similar device and which prevents the possibility of the log being displaced from the carriage while it is being turned.

BRAKE LEVER MECHANISM FOR CARTS AND WAGONS.—G. Manlove, Rushville, Ill. More particularly the invention concerns itself with that form of brake lever mechanism which comprises a segment with which a lever co-operates by means of a pawl so that the pawl will hold the brakes applied when the lever is thrown over to the braking position.

STUMP EXTRACTOR.—A. P. Branin and E. J. Wark, Portland, Ore. This machine extracts stumps or similar obstructions from the ground. The object of the invention is to provide a machine which is simple in construction, having means whereby the device

may be anchored and improved means for attachment to a stump or other obstruction which is to be removed

ROCK DRILL.—L. F. Sleade, Denver, Colo., and W. A. Sherwood, Courtland, Ariz. In the present patent the improvement relates to drills, the more particular purpose being the provision of a type of drill especially suitable for work in rock and similar hard substances, and possessing a number of constructional advantages whereby its utility is greatly increased.

MACHINE FOR MAKING COMPOSITE FABRIC.—F. Strauss and W. B. Fankins, New York, N. Y. An object here is to provide means for delivering a plurality of layers of material under proper tension to an assembling and folding device. Further to provide means for delivering a plurality of layers of material to a compressing device in a peculiarly assembled relation and under a proper tension.

BRISTLE DRYING MACHINE.—F. R. Zeuske, Toledo, Ohio. The intention in this case is to produce a machine which can treat a large quantity of bristles and which operates in connection with a drying current of hot air. The bristles are treated in such a way that they are turned over and over so that they become uniformly exposed to the heat during the drying process.

PNEUMATIC RELAY FOR AUTOMATIC MUSICAL INSTRUMENTS.—A. W. Lonsdale, 24 Woburn road, Bedford, England. The invention relates more particularly to relays such as are commonly employed in the "actions" of automatic piano-players and similar instruments or adjuncts thereto. The feature consists in the fact of the secondary valve being so mounted and guided as to be completely free to seat itself fairly upon the surfaces with which it alternately makes joint.

BREAKING OR GRANULATING MACHINE.—J. H. Spencer, New York, N. Y. For the purpose of granulating or breaking the meat of nuts and other material without bruising or crushing, use is made of stationary spaced jaws, and movable jaws adapted to pass between adjacent fixed jaws, said fixed and movable jaws having tapering sides and the wider faces of the fixed jaws being uppermost and the wider of the others being lowermost at their passage between the fixed jaws.

TYPE WRITER ATTACHMENT.—D. F. Maher, Watsonville, Cal. It is sometimes desirable to dictate directly to the typewriter so that the letter may be written at once without the intervention of a stenographer. In so dictating much time is lost by the one dictating and the operator and Mr. Maher seeks to devise a simple storm device whereby the operator may indicate to the dictator when the latter may proceed with the dictation.

TYPE WRITER STAND.—C. F. Goldino, Tampa, Fla. The objects here are to provide means whereby heavy records may be held in view of the operator while operating; means whereby the pages may be secured or clamped in flat position upon the copy holder; means whereby successive lines may be accurately followed by the operator; and means whereby the heavy and cumbersome record may be shifted easily.

MECHANICAL MOVEMENT.—F. L. Bowers, Jersey City, N. J. The movement is of special value in connection with flying, rowing, and exercising machines and in various other relations wherein it is desirable to cause a reciprocating member to feather in an arbitrary manner for the purpose of producing an efficient stroke.

CLUTCH.—W. E. Knoell, Minneapolis, Minn. This clutch will automatically release at the first revolution of the shaft after engagement. The invention is particularly adapted for use in the class of machines wherein a single rotation of the driving pulley is desired, and wherein the timing of such rotation is manually controlled.

HANDLING MACHINE FOR BASKETS.—F. L. Harrell, Jacksonville, Texas. This simple machine will operate automatically to feed in the wire stock, cut the wire to the proper length and form it into a handle. The machine then operates to attach the handle to the basket and clinches it in position.

GAGE FOR DETERMINING THE VELOCITY OF FLUIDS.—F. H. Crawford and M. B. Cashmore, Columbus, Ohio. The velocity of fluid may be ascertained with a knowledge of the statical pressure in one half of the gage by determining the variation of the levels in the two halves of the gage, which is readily determined by examination of a dial over which travels a hand which is secured to the gearing. A scale and glass tube are also provided for use when placing the fluids in the lower portion of the gage.

PROPELLER.—F. C. Gordon, Cleveland, Ohio. In this propeller the blades are reversible so that the shaft while turning continuously in one direction may be made to turn the vessel ahead or astern as desired. The invention provides a casing for the blades, the casing constituting not only a protective and retaining part but a bearing part as well. It is an improvement over a similar device in a patent formerly granted to Mr. Gordon.

BEER DISPENSING APPARATUS.—W. A. Westfall, New Albany, Ind. One of the objects of this improvement is to provide a device by which the manipulation of simple mechanism may cause the return of beer to the kegs, the cleaning of the coils, pipes and faucets, and the draining of these parts, thereby leaving the apparatus clean and ready for subsequent use.

ROAD WORKING MACHINE.—E. B. Winters, Coffeyville, Kan. The invention pertains more particularly to such machines as are used for grading roads, and which include substantially parallel beams carrying scraper blades adapted to engage the road surface, and means whereby the pitch of the blades may be adjusted to alter the depth to which they shall sink into the road surface.

BUSH HAMMER.—J. H. Sweetland, Hall Quarry, Maine. The inventor's aim is to provide means to more securely hold the teeth or blades in the head of the hammer, so that any lateral movement of the teeth or blades may be prevented, while at the same time it is possible to replace the teeth cutter with little trouble.

## Prime Movers and Their Accessories.

CONDENSER PUMP.—P. J. Pennings, Kiel, Germany. According to the invention the pressure chamber of the pump for the water of condensation is adapted to take up the air primarily compressed in the air pump and to raise the pressure of said air to that of the atmosphere. The pump used for the water of condensation is of the single acting type.

## Railways and Their Accessories.

SAFETY DEVICE FOR RAILROAD FROGS.—J. T. Watson, Osage City, Kan. This device is adapted to prevent a person walking on the railroad from catching his foot in a frog on the track, thus preventing the numerous accidents due to persons wedging their feet between the rails and being unable to extricate themselves before being run down by fast moving trains.

RAILWAY TIE AND RAIL.—I. J. Gray, Lawrence, Kan. This invention relates to railway ties and the object of the inventor is to produce a tie which is particularly adapted to be formed of metal and to provide a special construction of rail which facilitates its attachment to the tie. A further object is to provide special means for insuring that the tie will keep its shape. The railway ties constructed as intended can be readily formed from light sheet metal.

CAR MOVER.—F. E. Bailey, Rib Lake, Wis. The object here is to provide a device which is simple and serviceable in construction and inexpensive to manufacture which will automatically clamp itself on a rail to give a firm support for the lever as the latter is operated to advance a car along the tracks.

SIGNAL.—R. C. Brown, Hastings, Colo. An object of this inventor is to provide a railroad signal which can be removably mounted upon railroad locomotives, cars or the like, or on or near the railroad track, which can be reversed to present a different appearance or color, which can be easily cleaned when soiled, and which can be manipulated rapidly and easily.

MINE CAR WHEEL.—J. T. Parks and M. T. Davis, Jr., Charleston, W. Va. The main purpose of the present invention is to make use of a plug for holding the wheel on the shaft, with improvements for loosening the plug if the latter should become jammed against the shaft. Further to provide a plug for keeping the hub on the wheel which is not subject to the danger of rotating out of place, but which is held in place by means of an extension.

MERCHANDISE-TRANSFER SYSTEM.—G. Macartney, St. Paul, Minn. Generally speaking the invention consists of one or more unloading platforms, with one or more railroad tracks located adjacent thereto and a plurality of loading platforms with tracks adjacent thereto and with interconnecting tracks adjacent to said loading and unloading platforms, the relative heights of the railroad and miniature railroad tracks and platforms being so arranged that the floors of the cars on the various tracks will extend in substantially the same level as the floors of the adjacent platform.

RAIL CONNECTION.—H. Grass, Alvin, Texas. It is the usual practice to connect the meeting ends of rails by means of heavy fish-plates and screw bolts, leaving such ends otherwise entirely unsupported between adjacent cross-ties. The object of the inventor is to prevent certain results due to the above and other arrangements of imperfect and objectionable connections between rail ends and the lack of due support therefor.

ELECTRIC CONDUCTOR FOR RAILWAYS.—E. W. Ennquist, New York, N. Y. Primarily the object here is to provide in connection with one or both of the traffic rails of an electric railway, i. e., one of the rails on which the rolling stock travels as contradistinguished from other rails, an electric conductor or conductors for feeding the car motor, thus dispensing with the usual third rail or overhead wire conductor and avoiding many of the dangers and inconveniences resulting therefrom.

JOURNAL-BOX LID FASTENER.—T. H. Jore, Charleston, S. C. The improvement is in boxes for railroad stock, and resides in the construction of the lid and the parts of the body co-operative therewith to lock the lid in closed position, limit its sliding movement in the opening of the box, force the lid when closed, in a direction to bind the lid to the box body, and when open to frictionally retain the lid in an open position, and in constructing the box so that the locking means can be disengaged only by a special key.

## Pertaining to Vehicles.

VEHICLE BRAKE.—F. A. Sigemann, Newark, Ohio. The aim in this case is to provide a brake for use in connection with motor vehicles and the like, by means of which the vehicle can be brought to a sudden stop without arresting the rotation of the driving wheels, so that the strain upon the motor, incident to the sudden application of the ordinary brakes is obviated.

RUNNING-GEAR FOR WAGONS.—W. J. Orr, Merlin, Ore. In the present patent the purpose of the invention is to provide novel details of construction for a freight hauling wagon, which are light, strong and durable, enable a quick turning movement, largely prevent destructive wear, and that may be produced at a moderate cost.

MOTOR.—G. Keller, New York, N. Y. The object here is to provide a motor or explosion engine of the two-cycle type arranged to utilize the motive agent to the fullest advantage by giving continuous impulses in proper rotation to a plurality of pistons connected with the main shaft to insure a steady and uniform running of the engine and hence permit the use of the motor on automobiles and the like.

ANTISKID ATTACHMENT FOR VEHICLE-WHEELS.—T. T. Chalmers, New York, N. Y. The inventor's object is to provide a device, several of which are adapted to be attached at intervals to a wheel of an automobile or the like, to protect the tire and at the same time prevent the wheel from skidding.

VEHICLE-TRUCK OR RUNNING-GEAR.—W. S. Wills, Covington, Va. The improvement is in trucks and running gear, whereby the inventor reduces and distributes the jar or shock incident to contact of the wheels with obstacles in the roadway, and whereby the vehicle bed or frame to which the truck proper is attached will not be lifted as much as that one of the wheels which may pass over an obstruction. Thus in a vehicle provided with this attachment, springs may be dispensed with.

JOINT-COVER.—A. G. Williams, Sidney, N. Y. This cover for protecting a ball joint, comprises a flexible sleeve adapted to be opened out in the form of a flat sheet and provided with an opening on its side, with the walls of the opening formed of an elastic material and adapted to be expanded over the ball of the joint and closely fit around the member to which the ball is secured.

VELOCIPEDE.—M. Slotkin, New York, N. Y. Through the medium of the clutch a continuous movement can be imparted to the driving axle and when two clutches and accompanying parts are employed the forward motion of the vehicle will be positively uninterrupted, and when a single clutch is used the momentum of the vehicle after one movement of the pedal or lever will carry it forward until the clutch is again brought into active operation.

LOADING MACHINE.—G. Kruse, George, Iowa. This machine is especially adapted for loading manure into a wagon. An object of the invention is to provide a device capable of lifting large loads and of depositing them in a waiting vehicle without the use of engines or other power generators, the action of the machine depending entirely upon the power supplied by hand.

CARRIAGE-LAMP BOX.—B. E. Cole, Democracy, Ohio. The object of the invention is to provide a box or case, to be secured beneath the bottom of a buggy, to carry an ordinary stable lantern so that the lantern may act as a carriage lamp while driving, and as a lantern when out of the buggy or carriage and to serve also as a heater for the buggy or carriage.

## Designs.

DESIGN FOR A FABRIC FOR WINDOW SHADES OR SIMILAR ARTICLES.—A. A. Boeck, New York, N. Y. The design presented in this case is an original arrangement of vertical and cross lines which show an ornamental effect heightened by alternating the density of the rows of patterns. Mr. Boeck has designed another arrangement of cross and vertical lines embodying some of the effects of the denser band in the former design.

DESIGN FOR FABRIC.—D. Valentine, East Orange, N. J. In this fabric design the brilliant effect is produced by a broad mass of solid round discs one-quarter of an inch in diameter on a white background. The discs do not quite touch and are in perfect alignment, with a white line running through the centers of the discs up and down and across.

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

# Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 18th or will be sent by mail on request.

(12174) H. T. VanP. asks: 1. How longitude or sidereal time is determined by the moons of Jupiter? A. Longitude is determined from the eclipses of the moons of Jupiter, by having a table of these eclipses in Greenwich time. This is published every year in the Astronomical Ephemeris by the United States Naval Observatory, Nautical Almanac Division. The moment of the occurrence of an eclipse is observed in local time. The difference between the local time of occurrence and the Greenwich time of the same eclipse is the difference of longitude required. 2. Is there a formula for getting the equation of time without using tables? A. The equation of time is the difference between the time of the true sun and that of the mean sun. Tables are given for it in works on astronomy. One may be found in Todd's "New Astronomy," which we send for $1.50. This gives the equation of time for each five days in the year. 3. Having the tables of the equation of time for one year, say 1909, can the equation of time be determined for the next year or any year following? A. The equation of time is the same for each year. A table for one year is the same as for any other.

(12175) W. P. says: Would you please inform me what are dry cells composed of? What is the chemical used in them and how can I recharge them when their powers get diminished or worn out? A. There is little to be gained in recharging dry cells, if time or money are considered. The cement may be broken out at the top and a strong solution of salt ammoniac may be put in and allowed to soak down through the cell. This will take considerable time. Others have punched holes in the side of the outer jaw and set this in a glass battery jar which is filled with the sal-ammoniac solution. You will find in our Supplements 1383 and 1387, price ten cents each, valuable articles upon the making of dry cells. It would be better to make new cells than to repair old ones.

(12176) M. R. says: We are told that the earth spins around, making one revolution every 24 hours, which is really very fast for so large a ball. Does the envelope of air which surrounds the earth turn with the earth as though it were a part of the earth, the winds which we experience being minor disturbances in the lowest stratas of the atmosphere? If this envelope does turn with the earth as though the two were one, can you tell me why it does so? If it does not, why do we experience at times perfect calm on some of the highest points of the earth's surface? I would like to get a convincing answer either one way or the other. A. The air is a part of the earth, and a very heavy part of the earth. The weight of air above each square inch of the surface of the earth is 15 pounds, with some variations from time to time. This gives for the weight of the whole atmosphere 5,000,000,000,000,000 tons. The air moves with the earth as it rotates. If it did not we should have an east wind at the equator all the time blowing 1,000 miles an hour. This would tear everything off the earth and leave it a barren mass of stone. The winds which we have are due to the heat of the sun. Davies' "Elementary Meteorology," which we send for $2.50, will give you much information on such topics.

(12177) T. O. W. says: Will you kindly tell me if metal reinforcements have ever been successfully inserted and used in such materials as sewer tile where the clay was burned and glazed? Would it be possible to use iron in this way, or would the iron oxidize and also expand too greatly? A. We have no information as to metal reinforcement having been used in baked clay tile, but have no doubt that it can or could be so used, since it is satisfactorily used in glass. The difference between the expansion of iron and that of pottery is too small to set any internal stress when the former is imbedded in the material of lower heat conductivity and the metal sufficiently protected from oxidation as in concrete.

(12178) W. V. L. says: Will you recommend a paper on the subject of babbitting journal boxes for machinery? I am especially anxious to learn best method of pouring babbitt around a shaft, leaving a solid box and yet leaving the shafting loose enough to turn free and easy. You know it always shrinks tight on the shaft if the journal has not been tymbed in some way to prevent as the babbitt cools. I get along very well with split boxes, yet there is much about this I would like to read a good article on. Is there any process by which babbitt may be made to solder or weld to the inside of the cast iron box? Can they be tinned by the use of acid and the soldering iron as copper, so that the hot babbitt will adhere while it is being poured? If you have numbers of the Supplement covering this, ple-

portant subject of Babbitting Boxes in general, will you please point them out to me? A. We regret that we have no SUPPLEMENT numbers exactly covering the point you mention. A babbitt composed of 1 part of antimony to 4 parts of lead has excellent anti-friction properties, is hard, and shrinks almost not at all on cooling. The writer has had good success in casting solid bushings or boxes around small shafts with the above, and even with bronze, by coating the shaft thickly with lampblack (from a miner's hand lamp burning lard or similar oil), and then pouring the metal around it. The lampblack being pure carbon, makes as good a lubricant as graphite when mixed with oil.

(12179) F H says Will you please settle a dispute that has arisen on the following subject: A claims that it grows colder the deeper we go into the earth basing his argument on the fact that cold water oftenest comes from deep wells and that a certain iron mine is very cold at its greater depths, so much so that visitors are given overcoats to wear before taken down B claims that A's argument is entirely fallacious and based on special conditions that the fact is that the temperature increases as we go down into the earth, approximately at the rate of one degree for every fifty feet. A It is a well known fact that the temperature rises one degree for every 50 to 60 feet which we go down in the earth below the level of unchanged or constant annual temperature That there are cold springs is of course true There are also hot springs, boiling hot springs, in many places on the earth And the general statement which we made above is certainly true The subject is treated in all textbooks of geology We can sent you Scott's, one of the most recent and best, for $2.80 postpaid.

(12180) L. F says Please tell me what constitutes a horse-power for the steam engine, and from what did the name horse-power originate? What is vacuum? A The term horse-power means as the name implies, the power of a horse, and was established by James Watt, in order that he might have some basis of comparison of the power developed by his engines. He measured the work done by a heavy London draft horse of the Clydesdale or similar variety during short intervals by observing the weight it could lift against gravity, the horse of course walking on the ground and pulling horizontally on a rope led through pulleys, so that the weight rose vertically The unit horse-power, so established, was 550 foot-pounds of work per second or 33,000 foot pounds per minute i e, 33,000 pounds raised one foot in a minute, 330 pounds raised 100 feet, or 1 pound raised 33 000 feet per minute, but whereas few horses could do that amount of work for more than a few seconds together a 1 horse-power engine will go on producing that amount of work indefinitely so long as it is supplied with steam

(12181) W. K. B. says I am interested in knowing what kind of satisfaction dry colors ground with crude oil would give used as a cheap paint for such buildings as barns, etc. My idea is to let the crude oil take the part of linseed oil, the use of which would greatly reduce the price of this class of paint I am told by a painter that he used to work in the oil districts at his trade and that he had used a great deal of this kind of paint. A The experience of your friend who has tried it may be a better guide than our theory, but we should not say that the mixture of pigment with crude petroleum would form a satisfactory paint from any point of view except that of first cost Crude oil is not colorless or transparent and would discolor the more delicate pigments, making yellow, for instance, a rather dirty green Then again, linseed oil has the property of increasing in weight upon oxidation by exposure to atmosphere, thereby adding to its protective value, whereas the only constituents of petroleum preservative to metals from corrosion are volatile, and upon evaporation of its oils the paint made from it would have no value unless the pigment itself were preservative and capable of hardening into a continuous coat.

(12182) C A. R. B. says 1. Please inform me what weight a thousand cubic feet of hydrogen will sustain A One thousand cubic feet of hydrogen will sustain 70 pounds at normal barometer at sea level and the freezing point, 32 deg Fahr 2 The weight of a cubic foot of air at sea level and at 5,000 feet altitude, if you have the information at hand. A. A cubic foot of air at normal barometer and 32 deg Fahr weighs 0.08071 pounds. At an altitude of 5,000 feet under the same conditions the air will be about five-sixths as heavy, that is, when the barometer is normal at the sea level, at 5,000 feet above the sea the barometer will stand about 25 inches, or five-sixths as high.

(12183) J. M K. says As a reader of your valuable paper I would like to ask the following queries: 1. Is a mercury incubator thermometer liable to break or crack on being exposed to a sudden change of temperature from 104 deg. F. to 32 deg. F.? A. A mercury thermometer should not break by a sudden change from 104 deg. to 32 deg. Still it is not necessary to plunge such a thermometer into ice to test it. Make the change gradually and give time for the glass to take the new temperature. 2. [illegible] a telephone generator [illegible] A. [illegible] telephone generator is run by [illegible] a magneto generator It is provided with permanent magnets and does not require a field winding.

## NEW BOOKS, ETC.

THE ART OF THE BELGIAN GALLERIES. By Esther Singleton. Boston L. C Page & Co., 1909 12mo., 369 pp 48 plates. Price, $2.

The author has produced a most readable book, which will be valuable to the visitor to the galleries of Antwerp, Brussels, and Bruges. The book is intended for a help to the student in tracing the course of Flemish art by the notable pictures to be found in the Belgian galleries. The introductory part contains short biographies of the chief masters whose works are contained in the galleries, and descriptive matter relative to their places in the course of Flemish art together with some description of their individual art and their influence on others. In describing the art of the individual galleries, the general plan has been to deal first with the masterpieces of the collection and the works of the greatest masters grouping the latter irrespective of subject The illustrations are admirably selected and are beautifully reproduced in warm sepia tones. In comparing this volume with the preceding one on "The Art of the Netherland Galleries," the effect of religion on the development of the schools is very marked, for while the Protestant Dutch were painting portraits or scenes of domestic life as well as landscapes, the Roman Catholic Flemings were still painting large pictures of religious subjects in the old spirit of devotion Now that the whole world is turning with more and more interest to old Dutch and Flemish pictures, this volume will prove of great interest

CHATS ON OLD SILVER. By E L. Lowes New York Frederick A Stokes Company, 1909 12mo, 320 pp Price, $2

This sumptuous book is freely illustrated by 54 full-page illustrations and numerous line drawings in the text There is also a colored frontispiece The subject is a most fascinating one, for among all the objects of fine art which the amateur collects, there is nothing which is so easy to acquire and so satisfactory as old silver Fine furniture, choice prints, and goodly pictures are objects greatly sought after but they must be fine and bear the outward and visible sign of some master hand to be worth collecting They have also to bear the constant risk of deterioration, to withstand the continued fluctuations of taste, and consequent rise and fall of the market whereas old silver on the contrary has sound foundations there is no doubt about its date and market value It is writ so large that he who runs may read The making of a collection of old silver is literally within the means of the middle-class collector The author knows his subject well and treats the same with a breadth which is truly refreshing in a book for collectors by a collector The text is printed on beautiful light tinted paper most agreeable to the touch and to the eye, while the inserted plates are printed on the whitest of coated paper The section relating to hall marks and date letters is most valuable The sale prices which are appended give valuable indications of the market during the last few years.

THE SLIDE RULE. An Elementary Treatise. By J J Clark, M E Scranton, Pa. Technical Supply Company 18mo., 62 pp 1 plate

The author has been approached many times by engineers owning a slide rule, but who are practically unable to use it, with a request as to how to use it in certain cases. This has served to demonstrate that the instructions studied were not understood, and that they were so difficult, meagre, or ambiguous that the reader did not have patience to study them until he had mastered the intricacies of the rule. This is very true; for of the slide rules in existence many are not put to anything like their full use, owing to the fact that the principles have not been thoroughly mastered To the person who thoroughly understands three or four of the leading principles the slide rule is a wonderfully simple and easily operated instrument It is not necessary for him to remember any settings, and he can solve any case with ease and precision Bearing this in mind, the author has endeavored to explain these principles so thoroughly that they cannot be forgotten, and in such a manner that anyone with a fair knowledge of arithmetic can readily understand them The writer of this review may state that his slide rule has been given added value after a perusal of this little work.

DOCKHAM'S AMERICAN REPORT AND DIRECTORY OF THE TEXTILE MANUFACTURE AND DRY GOODS TRADE. Boston Dockham Publishing Company, 1909 Quarto, 642 pp Price, $6

This is the twenty-second edition of the forty third year of this most valuable publication There is no subject more difficult to deal with than the question of textile manufacture and this is the only book which will solve many of the difficulties. It has many excellent points, such as statistics on the looms in the United States, the number of cotton spindles, sets of wool cards, worsted combs, etc There is also a list of textile manufacturers arranged alphabetically by States, including Canada and Mexico also. There are separate lists for bleacheries, cotton dealers, cotton goods manufacturers, wholesale dry goods, dryers, finishers, and mercerizers, exporters, importers, print works, wool dealers, wool-hat manufacturers, and yarn dealers.

WIRELESS TELEGRAPHY AND HIGH FREQUENCY ELECTRICITY By H La V Twining, A.B. Los Angeles, Cal. Published by the author 8vo, 202 pp Price $1 50

The many amateur wireless-telegraph operators in this country use induction coils rather than transformers because the induction coil is convenient and because very little has been written on the subject of small transformers adapted for their particular uses The author of the present work goes into the subject of building transformers to take the place of induction coils and supplies the data necessary for building fourteen sizes of transformers of from one hundred watts to five kilowatts. While the theory of wireless telegraphy and high frequency apparatus is explained, this is done in a very simple manner so that it can readily be understood by those who have not had a course in electrical engineering. The construction described are eminently practical, and the result of the author's own experimental work

CHATS ON OLD EARTHENWARE By Arthur Hayden. New York Frederick A. Stokes Company, 1909 12mo, pp 496 Price, $2.

This beautiful book is accompanied by 150 illustrations and tables of over 200 illustrated marks. Five years ago the author published "Chats on English Silver" which was warmly received A great number of readers wrote to the author suggesting that he should write a companion volume dealing with old English earthenware The collection of old English earthenware, in the main is still within the reach of those who have slender purses, while English china within the last decade has reached prohibitive prices After a bibliographical sketch comes a glossary then a chapter on "How to Collect" for Beginners which is extremely valuable This is followed by chapters on Early Ware English Delft Stoneware Early Staffordshire Ware Salt Glazed Ware, Josiah Wedgwood Leeds and other factories, Transfer Printed Ware Staffordshire Figures Swansea and other factories Lustre Ware and Late Staffordshire Ware There are valuable lists of prices appended to every chapter The book is very handsomely made and is sure to merit the attention of all collectors

POTTERY OF THE NEAR EAST By Garrett Chatfield Pier New York G P Putnam's Sons, 1909 12mo, pp 175, 64 illustrations Price, $5 50 net

Many choice and remarkably preserved examples of the ceramic wares of this section of the Orient have recently reached our markets examples distinctive in material form and ornamentation Among these were found certain pieces of more than usual interest, since they provide us with new facts in regard to the dating of certain of these early mediæval ceramic productions To present these facts as concisely as possible is the purpose of this monograph which it may be added deals with the Muhammedan wares of every section of the Near East with the single exception of those of Saracenic Spain so ably treated of by Dr Van de Put.

CATALOGUE OF THE WORKS OF ART BELONGING TO THE CITY OF NEW YORK New York Prepared and issued by the Art Commission of the City of New York, 1909. Large 8vo, pp 241

The City of New York began its valuable collection of portraits in 1790 by requesting Gen Washington to permit Mr. Trumbull to take his portrait to be placed in the City Hall as a monument of the respect which the inhabitants of this city has toward him Since this time the city has been acquiring works of art of all kinds. Technically these works of art are under the charge of and they are passed upon by the Art Commission of the city of New York The constitution of this commission is most admirable Its present members are Robert W De Forest Frank D Millet John B Pine George B McClellan A Augustus Healy John Bigelow Arnold W Brunner, Charles Howland Russell Fred B Pratt and Herbert Adams Thus we have artists, sculptors officers of literary and artistic societies and museums, as well as a painter and a sculptor If it were not for this estimable body the city of New York would have foisted upon it most atrocious works This commission is an artistic safeguard of the city The book is a beautiful one, magnificently printed and it gives a complete *catalogue raisonné* of all the works in the possession of the city numbering several hundred. The plates are superbly executed

THE STORY OF DUTCH PAINTING By Charles H. Caffin. New York The Century Company, 1909 Square 8vo, pp 200 Price, $1 20 net

The tale of how the Dutchmen of the seventeenth century developed a new school of painting is a part of the story of the lives and fortunes of the Dutch people and to know something of the latter helps to appreciation of what these Dutch painters tried to do, and how they succeeded. Mr Caffin tells what the principal Dutch artists accomplished in portraiture in landscape and in the representation of the indoor and outdoor life of the people why they chose these subjects, and why they treated them as they did The result is a complete and readable handbook of Dutch art equally appealing to wide-awake young people and to adult students of art The reproductions of notable Dutch paintings add to the volume's value and interest

IN WILDEST AFRICA By Peter MacQueen, F.R.G.S Boston L C Page & Co 1909 12mo, pp 402 Price, $3

This is a description of a hunting and exploring trip through Uganda Victoria Nyanza the Kilimanjaro region and British East Africa, with an account of an ascent of the snow fields of Mt Kibo in East Central Africa and a description of the various native tribes. The book is admirably illustrated by a very valuable series of 64 plates from the original photographs taken chiefly by the author's traveling companion Peter Dutkewich It is also accompanied by a map showing the district under discussion The publication of this book is timely owing to the appearance of the interesting articles by ex President Roosevelt covering the same ground The contribution of Mr Dutkewich who is a Russian by birth but who has lived most of his life in America is most unique He is a professional outdoor photographer and has made 12,000 negatives in all parts of the country The author's text is clear and interesting and is an admirable exposition of life in this wildest part of the globe Equatorial Africa is one of the most fascinating countries in the world It allures and repels It is beautiful as an opium dream, baneful as nightshade One day a man is well and strong the next he is dead and buried But just as the Americans improved the conditions in Cuba and Panama so will the English, French and Germans probe into the sombre mysteries of Africa dispel the clouds with which it has been draped for five millenniums, and make it in a few decades, a land of light learning and liberty Few seem to realise that Africa is no longer the Dark Continent

THE ELEMENTS OF MACHINE DESIGN Part I General Principles, Strength of Materials, Rivets, Bolts and other Fastenings, Journals and Shafting, Couplings, Pedestals, Transmission of Power by Gearing, Belting, Ropes, and Chains By W Cawthorne Unwin LL.D, F.R.S New edition, revised and enlarged London Longmans Green & Co, 1909 8vo, pp 531 Price, $2 50

This treatise is intended to occupy a distinct field between works on applied mechanics and empirical books of rules and examples of machine details. In common with the former the scientific rules applicable to, and the design of machines are given with such an amount of clearness and explanation as is necessary to make them intelligible to readers acquainted with the general purpose of mechanics It has been aptly said that the engineer is a man who is continually being called upon to make up his mind but whatever it is after it is once decided it is irrevocable for it is transmitted into steel, iron and copper and cannot readily be revoked It therefore behooves the engineer to be posted at every possible point The book is a very valuable one and the fact that the practice is English does not seriously militate against it

SPRING FLOWERS AT BELVOIR CASTLE. By W H Divers London Longmans Green & Co 1909 8vo, pp 193 Price, $1 80 net

Belvoir Castle is one of the finest country seats in England The author is head gardener to his Grace the Duke of Rutland Owing to the large number of inquiries which he has received concerning the cultivation of the spring bedding plants in this garden he has been induced to write this beautiful little book which is a charming exposition of what landscape gardening really means The author hopes that many others will be led to cultivate these interesting and beautiful plants more extensively and thus make their gardens more beautiful in the early months of the year These hardy plants appeal to a large number of persons not only because of their beauty when seen in a mass, but because of their low cost and the small amount of labor required to take care of them during the summer months and for transplanting them in the autumn Thus they are adapted for everyone who has a garden The illustrations are from photographs taken by the author They show that he is not only an expert gardener but a photographer of no mean order

PRACTICAL HOUSE FRAMING By Albert Fair New York Industrial Book Company, 1909 108 pp, 98 illustrations, 12mo Price 50 cents

*The series of articles on house framing was recently published in* The Practical Carpenter Mr Fair the author of these articles has prepared them in the form of a practical text book for beginners and a reliable guide for journeymen It takes up the subject of braced frame construction, containing many useful hints and suggestions on these forms of house framing.

HOW TO MAKE TABLETS By Frank Edel Boston The Spatula Publishing Company 24 page pamphlet Price, 25 cents

Among the products of modern pharmacy none are more popular than compressed tablets, and it is a very easy matter for the ordinary druggist with a small expenditure to make tablets which are better than those of the larger manufacturers.

**QUESTIONS AND ANSWERS ON THE PRACTICE AND THEORY OF SANITARY PLUMBING. Vol I Drainage and Venting. Ninth Edition, revised and enlarged, by R M Starbuck. Hartford, Conn: The Bond Press Company, 1909 16mo, pp 164 Price, $1**

This little volume has passed through a number of editions, each one of which has been presented to the reader in a more valuable form than the preceding one The original purpose was to present the subject in as concise, brief and practical manner as possible The popular question-and-answer system is employed

**HINTS FOR CARPENTERS. Compiled and edited by Albert Fair New York Industrial Book Company, 1909 12mo., 144 pp., 101 illustrations Price, 50 cents**

This is a collection of practical hints for amateur carpenters and joiners and explains how to take care of their tools and make various appliances which will lighten their work The material has been taken from The Practical Carpenter and is a collection of ideas of practical men Some of the devices may appear very simple and elementary but the author does not hesitate to include them in the collection because of the possibility that they might in certain cases prove to be of the utmost value to the reader

**DYNAMOS AND MOTORS A Text Book for Colleges and Technical Schools. By William Suddards Franklin, Professor of Physics Lehigh University and William Esty, Professor of Electrical Engineering, Lehigh University New York The Macmillan Company, 1909 8vo., 489 pp Price, $4**

This is a physical treatise on dynamo electric machinery, taking up the subject in five parts. The first deals with electric current, the dynamo and the transformer and the measurement of direct current and alternating current Part II deals with direct-current generators and motors The theory of alternating currents is taken up in Part III, while alternating-current generators and motors form the fourth section of the book The fifth part is devoted to the practical operation of dynamos and an explanation of switchboards and switchboard appliances The book is primarily a text book adapted for the requirements of the student, and aims to give him a good basis of theory as well as a practical conception of the direct and alternating current dynamos and motors

**THEORY OF STRUCTURES By R. J Woods, M E, M Inst C E London Edward Arnold 1909 8vo, pp 276, 157 illustrations Price, $3**

This new volume although self-contained and independent of "The Strength and Elasticity of Structural Members by the same author forms a continuation of the previous work suitable for very advanced students and draftsmen engaged in structural design The elemental parts and formulæ of the former volumes are extended and utilized for a determination of the design of masonry and steel structures. Experience in the practical design of structures and a deepening sense of its importance has convinced the author of the great merit of presenting examples for study in a clear and intelligible form Consequently a large part of this book has been given to the working out of practical examples. It is a very useful book for any engineer

**ONE THOUSAND WAYS AND SCHEMES TO ATTRACT TRADE. By Irving P Fox and B. A Forbes Boston The Spatula Publishing Company Small quarto 203 pp Price, $1**

This little book is filled with one of the best schemes for attracting retail trade which we have ever seen and it is well worth the price charged for it.

## INDEX OF INVENTIONS

**For which Letters Patent of the United States were Issued for the Week Ending January 18, 1910.**

**AND EACH BEARING THAT DATE**

## A NEW ERA OF THE AMERICAN LOCOMOTIVE.

(Concluded from page 100.)

Atlantic type and the six-coupled type which succeeded it in fast passenger service. Commencing at the tender, which is of huge size in itself, we note that it is carried on two six-wheel trucks, a novelty in tender construction. The tank capacity is 4,000 gallons of oil and 12,000 gallons of water. The boiler, 6 feet in diameter, has 202 square feet of heating surface in the fire box, 3,275 square feet in the fire tubes, and 1,279 square feet in the feed water heater tubes, making a total of 4,756 square feet. In the superheating and re-heating section there are 1,121 square feet of tube surface.

The firebox is built up of steel plates, flanged to a channel section and riveted together with stay plates riveted in between the opposite flanges of the outer and inner shell. The fire tubes, 21 feet long, terminate in a combustion chamber, 10 feet, 9 inches long, which contains the super-heater and the re-heater. The front combustion chamber, which forms the feed water heater, contains 417 tubes, 2¼ inches in diameter by 6 feet 8 inches long.

The boiler with its super-heater and feed water heater extension is connected rigidly to the frame in which are carried the pair of trailing wheels, the six coupled drivers, and the high pressure cylinders. The low pressure cylinders, the forward truck and the four coupled drivers are carried in a separate frame and the weight of the forward portion of the boiler, feed water heater, etc. is carried upon this forward truck by means of two sliding bearings which allow the frame to move laterally underneath the boiler, as the locomotive enters upon a curve. This necessitates employing a flexible steam pipe for conveying the steam from the re-heater to the low pressure cylinders and the necessary flexibility is secured by using both slip and ball-and-socket joints in the steam pipe. Piston valves are used with both high and low-pressure cylinders, and the valve motions are of the Walschaert type. There are two high pressure cylinders 24 inch diameter by 28 inch stroke, and two low pressure cylinders 38 inch diameter by 28-inch stroke. The driving wheels are all 73-inch diameter.

The general construction of the freight locomotive is similar to the passenger locomotive, but the dimensions, weights and power are, of course, much greater. The boiler is 7 feet in diameter, works under a pressure of 220 pounds, and has a total heating surface, including the feed water heater, of 6,631 square feet. There are also 1,745 square feet of super-heating and re-heating surface. There are two high pressure cylinders, 26 inches in diameter by 34 inch stroke, connected to eight-coupled drivers 63 inches in diameter, and two low-pressure cylinders 38 inches in diameter by 34 inch stroke connected to eight-coupled 63 inch drivers. The tender contains 4,000 gallons of oil and 12,000 gallons of water. The engine alone weighs 231¼ tons, and the engine and tender together weigh 350 tons. The total pull on the draw bar maximum power is 54 tons.

It is no exaggeration to say that these locomotives mark a new era in American locomotive practice, for although the Mallet system, super-heating, feed water heating and compounding have been tried out separately on various locomotives, this is the first time that these refinements have been embodied so completely on a single type.

## HOW AN AMATEUR CAN FIND HALLEY'S COMET.

(Continued from page 102.)

it. It appeared like any one of the many faint stars in the field of view. I should think it was about the eleventh magnitude on November 30th. The ephemeris makes it a little fainter, but as stated in the SCIENTIFIC AMERICAN

(*Continued from page 113*)

lately, it has been growing brighter quite rapidly of late

In looking for a comet one must not be too credulous, and think that the first object he sees is a comet Many times I thought I had found the comet and could see even the tail, but it proved to be merely a star elongated by the shaking of the telescope

Now the same manner of proceeding may be applied when the comet is near any other star, though it will not soon be so desirably located as on the evening of November 30th After the comet is bright enough so one can see its tail and head, one would not need to go to so great trouble but could systematically search a limited and definite area near it, and in a short time would be able to pick it up But it is not expected that it will be a very conspicuous object in a small telescope before the close of winter or early spring in the meantime the ambitious amateur astronomer can satisfy his interest by studying it in this manner

As an aid to those who may wish to try this plan, it may be observed that the evening of February 5th is favorable because of the comet's proximity to Epsilon Piscium Epsilon Piscium is in R. A. 0 hr 58 min, and Dec 7 deg 24 min From the ephemeris given for February 5th the following is its location on that evening R A 0 hr 57 min, and its Dec +8 deg and 11 min Similarly it will be found close to Delta and 62 Piscium on February 17th, and March 5th it will be just north of 51 Piscium Its motion is much slower during February than for the two preceding months, and so its location ought to be an easy task for the evenings immediately before and after these dates

Where the neighboring star is not as conspicuous, as in the case of Aldebaran one must study the constellation and familiarize himself with the stars in it until he can locate the desired star This is often somewhat tedious, as a few weeks ago, when I tried to locate it among the many small stars in Taurus directly above Orion It is, however, a helpful study for the amateur

I had a very gratifying and profitable study on the evening of January 14th, as may be seen by the cuts January 13th was the evening of nearest approach to Omicron Piscium, but as this was a cloudy night I decided to try the following night I had searched but a moment or two when it appeared in view I have seen it two or three times since November 30th, but it has never appeared so distinctly as on this evening It is still faint, though but a few seconds of arc in size, and could be easily passed over if the observer is not careful It looked more like a small nebula I could not state definitely but it appeared as though it had a faint nucleus. But the most gratifying result of the evening's study was the unmistakable motion detected as is clearly shown in the cuts Stars *A* and *B* were about twenty minutes of arc apart. The amount of motion could not be determined accurately with the 45-power, and the comet is still too dim to use the higher powers. I have had no further opportunity as yet to pursue this phase of the study but shall at the earliest possible moment It will suggest a problem for other amateurs I anticipate for many other amateurs as much delight in the scrutinizing of Halley's comet as I have already had

It is estimated that the German Empire has nearly 35,000,000 acres of forest, of which 31.9 per cent belongs to the State German forestry on scientific lines has resulted in raising the average yield of wood per acre from 20 cubic feet in 1830 to 65 cubic feet in 1904 During the same period it has trebled the proportion of the sawn timber secured from the average cut. In fifty-four years it increased the money returns from an average acre of forest sevenfold, yet to-day the forests are in better condition than ever before

NEW YORK, SATURDAY, FEBRUARY 5th, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## LESSONS OF THE PARIS FLOOD

IT is rather surprising that in all the voluminous descriptions of the Paris flood, which have been published in America, there has been given no complete analysis of the meteorological conditions which have turned the usually gentle and tractable River Seine into a raging torrent, and wrought unbelievable havoc in the far famed and beautiful city of Paris. It seems unlikely that any mere rainfall in the watershed of the Seine could have been sufficient to produce the present enormous flood, and it is probable that a great part, if not the major part of the flood water, is due to sudden melting of the snow in the mountains and on the higher levels.

Apart from the extreme suffering and personal inconvenience resulting from the flood, the most serious aspect of the calamity is the disastrous effects which must surely result from the inundation of the foundations of the city, and the flooding of its labyrinth of subways and sewers by a vast volume of water of great depth pressure and velocity. It is a fact, well understood by engineers and architects, that foundation material which is perfectly stable in the dry condition, may lose much, if not all, of its supporting power when it becomes saturated, and particularly, if, as in the present case, the ground adjoining the foundation is full of such voids as are represented by subways, sewers, cellars and other excavations. A substratum which will remain stable under normal conditions, may begin to flow or slide when it is saturated, in which case heavy cracks will appear in the superincumbent walls, if indeed the building be not thrown down altogether.

Furthermore the cabled reports, referring to caving streets, bursting sewers and collapsing subways, indicate that another most destructive action of the water must be actively at work. We refer to the subterranean flow of water under pressure along the face of foundations, subways, sewers and other subterranean masonry work. Where such flow occurs, as for instance along the outside of a sewer, there is liable to be a washing away and displacement of the soil or other material, and where the sewers are filled with water under hydraulic pressure due to a considerable head, such as exists in the flooded district of Paris, it can easily be seen that, having but little strength to resist an outward thrust, they would be easily burst open, particularly if, as suggested, the enclosing soil had been washed away by the flow of water along their outer surface. Only when the floods have subsided and a full examination can be made, will the full measure of the present disaster be ascertained, but the probabilities are that the rebuilding of sub-surface construction will have to be done on an enormous scale.

Unquestionably, one result of the flood will be the undertaking of public works designed to prevent any repetition of the disaster. An obvious plan would be to build a masonry retaining wall, or levee, throughout the whole length of the city and for some distance above it, carrying the work to a height sufficient to prevent any future overflow. So enormous has been the volume of water that has come down, that unless the walls were carried to an inconvenient height, it would be necessary to increase the cross sectional area of the channel either by dredging, which is practicable, or by widening, which because of the great value of the property that would have to be condemned for this purpose would seem to be out of the question.

There can be little doubt that the overflow at Paris has been greatly increased by the presence of so many masonry bridges, each of which embodies several heavy masonry piers that greatly reduce the area of the channel, and if the municipal engineers undertake a sufficient enlargement to absolutely prevent future overflows the question of the obstruction presented by these bridges must surely come up for consideration. Judging from the reports it would seem that not only the piers, but the superstructures of the bridges themselves have served to dam the waters and spill them over the adjoining banks.

If the masonry structures were replaced by suspension bridges or single trusses spanning the entire channel from wall to wall, a great step would be taken toward the prevention of future floods. But would Paris, the beautiful, submit to the removal of so many monuments of her architectural genius as are afforded by the present succession of picturesque stone arch bridges.

## THE NEW YORK DEEP TUNNEL WATER SUPPLY.

JUDGED from the standpoint of sound engineering and practical utility the plan to carry the new five hundred million gallon per day Catskill water supply through the length of Manhattan Island in one large deep tunnel, cut through the everlasting rock, is one of the most commendable projects ever brought before this city, and we feel that a strong protest should be made against the attempt to discredit this enterprise, which is now being made by certain more or less interested parties.

It is unfortunately a fact that in this age of sensationalism there is no more fruitful field for the panic-monger and scarehead writer than that of engineering works of great magnitude, for such works deal with the stupendous forces of Nature, developing her latent energies on a grand scale, and holding them for beneficent uses only by the curb and bit of technical knowledge and sound engineering judgment. It is the easiest thing in the world, by a little juggling with figures and a large mis-statement of fact, to write a sensational article (or a series of them for that matter), that will lead the lay public to believe that the project under discussion is ill conceived and pregnant with big disaster. For a notable instance of this it is sufficient to refer to the agitation against the construction of the Panama Canal on the plans which are being so successfully followed. Now, the citizens of New York may rest well assured that the engineers who have staked the city's welfare and their own reputation upon the construction of a huge water-supply tunnel, from one hundred and fifty to two hundred feet below the surface of Manhattan, have not committed themselves to the scheme without the most exhaustive examination of the physical conditions, and the clearest evidence that in economy, durability and public convenience, the tunnel will be a great improvement over the original plan of conveying the water in multitudinous pipes laid near the surface of the ground.

The proposed tunnel, which will vary in diameter from 11 to 16½ feet, will extend from Hill View Reservoir near Yonkers, below the Bronx, the Harlem River and through the full length of Manhattan Island, and thence, below the East River, to a terminating point near the Atlantic Avenue Station of the Long Island Railroad. From this point pipe lines near the surface will extend under the Narrows to Staten Island and northeast into Brooklyn.

At the Hill View Reservoir at the north a 300-foot shaft will be sunk, from the bottom of which the great tunnel will be driven to the south. It will be constructed at sufficient depth (generally from 150 to 200 feet) to insure its lying everywhere in rock sufficiently solid to withstand, without leakage, the great internal pressure of the water, and as a further safeguard, it will be lined throughout its length with concrete. The total length of the tunnel will be seventeen and one-half miles and at 4,000 feet intervals construction shafts will be sunk from the surface. When the job is completed these shafts will serve as up-take shafts, with connections to the surface system of pipe distribution.

The most valuable advantage of the deep tunnel method is that in Lower Manhattan, Brooklyn and Staten Island, the water will be delivered at a greater elevation by about 100 feet than would be possible if the surface pipe lines were used, and water will be available without pumping on office floors up to a height of 260 feet above tide level. This great difference is explained by the fact that the frictional resistance to the flow of the water in the many relatively small surface pipes is largely eliminated by carrying the whole mass of water in one large single conduit. Other advantages are that, since the tunnel can convey as much water as thirty 4-foot pipes, the cost of construction and the annual charges will be about 50 per cent. less, that there will be no interference with subways and sewers, and no opening up of streets during construction or subsequently for repairs, that failure by breakage will be impossible; that there will be a great volume of water at hand in any locality for the control of large conflagrations, and lastly, that by cross-connection of the tunnel with the existing water-supply system, the latter can be safeguarded against any scarcity of supply or other serious emergency.

## OUR LATEST AND FINAL RECIPROCATING ENGINE BATTLESHIP.

THERE is no denying the fact that the Engineering Corps of the United States Navy view with no little sentimental regret, and a few of them possibly with some practical apprehension, the passing from our navy of that faithful and highly developed prime mover, the multiple-expansion reciprocating, marine engine. But if, because of the ever growing efficiency of the steam turbine, the reciprocating engine is in an advanced stage of obsolescence, it is gratifying to realize that in the United States battleship "Delaware," the last of the reciprocating engine battleships, it has shown that in the most important matter of steam economy, it is perfectly well able to more than hold its own, a fact which is highly gratifying, both to the Bureau of Steam Engineering who made the designs and to the Newport News Shipbuilding Company, the builders of the ship who constructed the engines.

The "Delaware," which is a sister ship to the North Dakota," is identical with that vessel in everything but motive power. She is driven by two vertical four-cylinder, triple-expansion engines, which embody the very latest developments of the type, with piston valves, forced lubrication and high rotational speed. Steam is supplied by water-tube boilers, running under forced draft, and provided with super-heaters, and feed water heaters.

The contract called for the development of 25,000 maximum horse-power and a speed of 21 knots. In the trials the engines developed a mean horse-power, on five runs over the mile, of 28,576 and a mean speed of 21.44 knots. The maximum horse-power developed for a single mile was 30,000, and the maximum speed 21.98 knots. Interest, naturally, centered on a comparison of the performance of the "Delaware's" piston engines with that of the "North Dakota's" turbines, and although the turbines drove the ship at higher speed, and with a smaller coal consumption per horse-power, the reciprocating engines of the "Delaware" showed a superior efficiency at all speeds in the consumption of steam. Now, while superior fuel economy may be and is often affected by the quality of the coal and the degree of skill of the fireman, and, therefore, may be credited more to the stoke-hole than to the engine room, the steam or water consumption is determined almost entirely by the efficiency of the engine, and it is on this last basis of comparison that the engines of the "Delaware" have made such a remarkably fine showing.

In the 24-hour run at 19 knots the "North Dakota" burned 295 tons of coal, with a water consumption of 15.92 pounds per horse-power per hour, and the "Delaware" 315 tons with a water consumption of 14.52 pounds per horse-power per hour. On the 24-hour run at 12 knots the "North Dakota" burned 105 tons with a water consumption of 23.94 pounds, and the "Delaware" 111 tons with a water consumption of 21.03 pounds per horse-power per hour. The total water consumed per hour by the turbines of the "North Dakota" at 12, 19, and 21 knots respectively was 76,000 pounds, 238,000 pounds and 349,000 pounds. The respective consumption for the "Delaware" for the main engines was 55,000 pounds, 205,000 pounds, and 312,000 pounds. These figures, considered on the score of steam economy, are greatly in favor of the reciprocating engine, and they indicate that the cruising radius of the "Delaware" is considerably larger than that of the "North Dakota."

Why then, it may be asked, is the government committing itself to the steam turbine as the drive for future battleships? The answer is, first, that the "Dakota's" turbines have been greatly improved upon in later models. The number of expansion stages has been increased, and the steam economy has been improved (as shown by recent tests of the Curtis turbine both in England and Germany) until it equals and even exceeds the figures obtained by the best reciprocating marine engine. An even more important consideration is the fact that the steam turbine, with fewer working parts subject to breakdowns, is a far more reliable engine. It can be driven all day long at the highest speed, without incurring any additional risk of failure; whereas when the reciprocating engine is forced to full power for a continuous run, there is always present, even in the best-constructed engines, the risk that some minor but essential part of the mechanism—a rod, a bearing, etc.—may fail and throw the whole engine out of commission.

---

The French Deputies were presented recently with specimens of the new aluminium coinage with which it is proposed to replace the bronze coins in France. The 10 centimes piece is described as "something between a counter and a trouser button," and is said to be even less attractive in appearance than a nickel coin, and to be "ugly and unhandy." The "sou" is much the same, but, of course, rather smaller, and it is expected that both, if they are adopted, will cause considerable confusion.

## ENGINEERING.

An experimental road has been constructed at Truro, which it is claimed has the advantages of being resilient, mud and dust proof, noiseless, and requiring no removal of the old surface. It consists in spiking down on the roadway sheets of expanded steel similar to those so largely used for the reinforcement of concrete, and laying over it a 3 inch depth of ordinary road material treated with coal tar, and rolling well in.

The final plans of the new Argentine dreadnoughts have now been passed. The ships will be called "Rividavia" and "Moreno." They will be of 25,000 tons displacement, and carry twelve 12 inch, twelve 6-inch, and twelve 4-inch guns. The speed will be 22 knots. There will, it is said, be two funnels and two skeleton masts of the new American type. The whole of the twelve big guns will bear on either broadside. The contract for these ships has been awarded to the Fore River Works, and in view of the fact that there was keen competition for this order among the leading shipbuilders of the world, the securing of this contract is a high tribute to American shipbuilding.

A new railroad company has been organized to build a line from Tesiutlan, State of Puebla, through the State of Veracruz, to the port of Nantla, says the Mexican Herald. The $2,500,000 gold capital has all been subscribed, and Engineer Leopoldo Villareal, a member of the board of directors, says that the line will develop a region rich in fruit, sugar, coffee, oil, etc., and that the freight on the lemon trade alone will pay the expenses of the road. A branch line will also be operated between Papantla and Misantla.

According to the United Service Gazette, the first airship for the British navy, which is now being built by Vickers, Sons & Maxim, will be the largest vessel of the kind in existence. It will be over 500 feet in length and driven by two motors of 200 horse-power each, which will be capable of driving the vessel at 45 miles an hour in still air. The nominal lifting power will be 20 tons, although its usual load, according to this authority, will not exceed five tons. It will be of the rigid type as this is considered to be best adapted for naval purposes.

There are over 400 miles of railway now in operation in Guatemala and various extensions are in prospect. One of these contemplates the building of a line from Zacapa on the Northern Railroad, about 100 miles from the sea, to Santa Ana, on the northwestern frontier of Salvador, where it will connect with the British railway already built, and thereby with the capital of Salvador. Much of the coffee now grown in that republic will thus find an outlet to the Atlantic of which it has long been in need, and it is highly probable that the bulk of the import trade to Salvador will also be conducted along this route.

In his first annual report, Secretary of the Navy Meyer asked for only two battleships and one repair ship. These battleships he recommends should be of the "all-big-gun" type. They will complete the squadron of eight vessels of that type. A repair ship is extremely desirable, in order that the fleet may be made more self-sustaining. Mr. Meyer favors the building of practically all the new vessels under contract with private shipbuilding concerns, not only because these industries should be fostered, but also because the construction is more economical when done by private concerns than at the government navy yards.

There is a bill before Congress providing for a bond issue of $30,000,000 for carrying on the work which is now under construction and contemplated by the United States Reclamation Service. A complete description of this noble project for bringing under cultivation arid and semi-arid regions of the West was given in the Middle West Number of the SCIENTIFIC AMERICAN of December 11th, 1909. It is expected that by the close of the next year about two million acres will have been reclaimed at a cost of $70,000,000. When the system is completed some thirty million acres will have been recovered and opened for settlement.

We have received the report of the Public Service Commission of the First District of the State of New York, which contains some interesting facts. The number of accidents in street and steam railroads within the city of New York was 56,481 in 1908, while in 1909 the number was reduced to 52,618. The number of persons killed decreased from 444 to 325, which is an encouraging decrease. The service rendered by the transportation companies is now better than ever before judged in proportion to the physical conditions and the volume of travel. This is largely due to the orders of the Commission. The minimum of service is continued a much longer period than heretofore, and the rush-train service has been increased. The matter of adequate service is a serious problem; for during each 24 hours, passengers, equal in number to about 85 per cent of the population must be carried. Fully one-third of all the passengers traveling in one direction during the day are carried in two hours out of the twenty-four.

## ELECTRICITY.

The United Improvement Association of Boston is urging the electrification of Boston railroad terminals. It is considered very probable that the matter will be taken up by the Massachusetts Legislature. A rough estimate of the cost of electrifying the terminals and suburban lines is placed at between $50,000,000 and $70,000,000.

The Fifth Annual Electrical Show, which was held in Chicago from January 15th to 29th was unusual for its beauty of decoration. The Coliseum where the exhibition was held was roofed with a canopy of tinsel and ribbons which were lighted up by means of two batteries of searchlights. The colored lights thrown on the gold and silver tinsel produced an extraordinarily splendid effect.

Electric power is furnished to Helsingöre, Denmark, from Sweden by means of a cable which runs under the narrow sea separating the two countries. The power is generated at a 300 foot fall of the Laga River in Sweden and is conducted to the coast by means of cable, where it connects with a submarine cable three miles long. The transmission of power by means of a submarine cable is quite unusual.

A demonstration of the use of electricity as an anæsthetic was recently made in Hartford, Conn., where a patient was thus anæsthetized while four frozen toes were removed from his foot. For the electrodes two zinc plates were used, one applied to the groin and the other to the ankle. During the operation the patient, who was blindfolded so that he would not witness the work of the surgeons, felt no pain and chatted and talked in a natural manner. When the operation was over he experienced no after effects.

From time to time estimates of the power of a lightning discharge are published which would give one the idea that every discharge represents an enormous current. On this point Prof. Elihu Thompson, lecturing at Princeton University on "Atmospheric Electricity," recently stated that "we must, however, be cautious not to exaggerate either the current or the potential present in a lightning flash. The current in a flash may at times be only a few amperes or may in a heavier discharge reach perhaps hundreds or approximately in extreme cases some few thousands of amperes. It is doubtful if the potential much exceeds at any time more than a few millions of volts as it is probable that small local breakdowns start the disruptive process which then extends through miles of length."

Following the recent attack on amateur wireless telegraph operators, which has resulted in the presenting of a bill before Congress to limit their activities, the amateurs are banding themselves together to resist any action which would interfere with their liberties. They claim that any experienced operator can pick out from a dozen sets of signals sent at the same time the one which he wishes to hear as each operator has his own characteristic method of sending a message which is as easily recognizable as the voice of one man in a crowd. Also that if the professionals care to go to the expense of installing the necessary apparatus they can cut out all the signals except those they wish to receive. While there are many thousands of amateur stations in this country very few of them are capable of transmitting a message more than a few miles and hence the amateur trouble is not to be gaged by the number of amateur stations but only by the number of those few stations which can transmit to over a hundred or two hundred miles.

The new Egner and Holmstrom microphone transmitter was lately given a test on various long distances starting from Stockholm. Conversation could be heard as far as Paris, which is an exceptionally long distance for telephones on the continent, or about 1,260 miles. The transmitter is based on the use of a light steel cylinder or flat box placed between the diaphragm and the carbon grains, so as to press with the flat bottom of the cylinder on a large surface of the grains. It will carry as high a current as one ampere and is thus exceptionally strong. The tests were carried out by the Swedish telephone administration, using a loop which passed through a distant city and then returned to Stockholm and to a subscriber's instrument. Switching in the old transmitter and the new one allowed a good comparison to be made. Speech could not be heard on the standard system, but it could be well heard when the new transmitter was used on lines such as Stockholm-Helsingborg and return, or 1,920 miles. Tests were also made between Stockholm and Berlin, and at this distance 780 miles, speech was as clear as on 100 miles of line on the standard system. Good results were had between the city and Cologne, or, 900 miles, after which the coupling was made with Paris (1,240 miles) via Frankfort and Hamburg. A local line leading from Stockholm to Sundsvall (350 miles) was added to this, making 1,710 miles in all and speech sent from Sundsvall to Paris could be well heard.

## SCIENCE.

During the month of January, 1910, four comets were at one time in the heavens. The first of these is Halley's comet, the second Winnecke's, rediscovered at the Observatory de la Plata on October 31st by Poro, the third is Daniel's, and the fourth Innes'.

The Austrian Ministry of Public Works is trying to settle upon a place where radium may be sold, and the price to be charged. The question came up when a quantity of ore shipped from Joachimsthal was found to contain no less than one gramme of radium. The price of this small quantity has been fixed at 380 crowns ($77.14) a milligramme. Those who contemplate purchasing radium may have their addresses entered at the Ministry of Public Works in order to receive information as to quantities and current prices of radium.

Dr. E. G. Acheson was presented with the Perkin medal at a recent meeting of the Chemists' Club. In presenting the medal Prof. C. F. Chandler traced the history of the decoration and told how it had been conferred upon Sir William H. Perkin, Dr. J. B. Francis Herreshoff, and Dr. Arno Behr. Dr. Acheson received the medal for discovering entirely new materials suitable for many purposes and now indispensable to the world. The substances with which Dr. Acheson's name is associated are carborundum, deflocculated graphite, and Egyptianized clay.

The New York Aquarium had a greater number of visitors during the year 1909 than ever before, the attendance being 3,803,501, an average of 10,417 a day. These figures show that the Aquarium has a greater patronage by the public than all the other museums of the city including the Zoological Park combined, and 1,800,000 more, for the same period than the New York Hippodrome which has probably the largest attendance of any theater in the city. These figures are unequaled by those of any other museum in the world of which statistics are available.

The first spectroscopic observations of Halley's comet, made at Meudon by Deslandres and Bernard, reveal clearly marked discontinuities in the spectrum of the comet. The faint continuous spectrum is crossed by distinctly stronger lines, especially in the ultra-violet region. On December 6th the comet showed a nearly circular nucleus from which extended two curved rays of feeble brilliancy, but distinct, and resembling in form the antennæ of an insect or the prongs of a two-pronged fork. The direction of these rays was such that it appeared scarcely possible to attribute them solely to the repulsive force of the sun. On the following day these appendages were no longer visible and the general brightness of the comet appeared to be diminished. These first observations show that the comet is already self-luminous and that its light is due partly to incandescent gases.

An asteroid, which appears to be a previously unrecorded member of the family, has been discovered by Boinot of the Paris observatory. In examining a photograph made on October 19th Boinot observed a faint linear trace. As the star images on the plate were perfectly round and sharp, it was evident that the trace was either a defect in the photograph or the impression made by a planet. In order to verify the observation, another photograph of the same part of the sky was made on October 23rd. The second plate showed the trace, a little to the southwest of its former position. It was, therefore, certainly due to an asteroid, which appeared to be of the eleventh magnitude. The discovery was immediately reported to the astronomical bureau of Kiel, where the asteroid was provisionally designated by the symbol 1909 J D. Since the remarkable discoveries made by the Henry brothers the search for asteroids has been carried on almost exclusively by German and American astronomers.

The French journal Le Radium describes a long series of experiments made by Blanc, of Rome, in regard to the presence of thorium in various earths and rocks. The proportions of thorium found expressed in millionths of the weight of the mineral, were as follows: Roman vegetable earth, 14.5, granite from the Vosges Mountains, 20.7, granite from Lake Maggiore, 31.4, various specimens of syenite, 63.0 to 82.8. The experiments of Joly relating to the rocks of the St. Gothard tunnel, gave the following quantities of thorium (in millionths): 5.10 in the weathered sedimentary rock near Tessin, 11.8 in the schists and 16.5 in the granite and gneiss of the Finsteraarhorn, but Joly found also similar quantities of uranium and about 1 ten-millionth as much radium. The inference is that thorium exists everywhere, in all rocks, in sea water, etc., and it appears not unlikely that with the aid of sufficiently exact methods, it would be found in all substances. Blanc has calculated the quantity of heat disengaged by the thorium compounds in the rocks and has found it twice as great as the heat produced by the elements of the uranium-radium family in the igneous rocks which were examined by Strutt. Hence it appears that thorium must play a considerable part in the radioactivity of the earth.

# A NEW STORAGE BATTERY STREET CAR

## ANOTHER EDISON INVENTION.

The announcement was made about nine years ago that Thomas A Edison would soon place on the market a storage battery that would be much lighter and of greater capacity than the usual battery and provided with positive and negative elements that would not deteriorate because in place of an acid an alkali would be used for the electrolyte Much was promised for this battery, and a year or two later it appeared The positive element consisted of nickel oxide interspersed with layers of graphite and packed in perforated nickel tubes, while the negative element consisted of iron oxide and the electrolyte was potassium hydrate Both elements were supported in nickeled steel grids The battery weighed about half that of the usual storage battery of the same capacity It showed no serious effect when rapidly discharged, and no damage resulted from overcharging Shortly after the batteries were placed on the market it was found that the graphite became oxidized and interfered with the output. After considerable research it was discovered that chemically pure nickel could be substituted for the graphite and would not become oxidized in use But soon another difficulty developed The nickel was packed in tubes of square cross section and these tubes would buckle or bulge outward, permitting the powdered nickel oxide to filter down over the pure nickel layers and insulate them Then it was determined that a round tube would have to be used which would withstand the pressure of the nickel oxide The problem of producing such tubes economically was a serious one. They had to be about the size of a lead pencil, namely, quarter of an inch in diameter and four inches long, with the sides finely perforated. A machine was eventually built which made the tubes out of perforated nickel ribbon. The ribbon was wound spirally with the edges of the coils interlocked and fastened together during the coiling process. A vast amount of money was spent in solving this one problem of the battery.

Shortly after the batteries were first put on the market they were withdrawn on account of the defects above enumerated, and about two years ago when the battery was finally completed in its present form a large number were sent out to be tested on auto-

(*Continued on page 133.*)

The car weighs but five tons complete and its construction represents a radical departure from common practice

Interior of the car with the seats raised to show the batteries placed in the steel girders.

A NEW STORAGE BATTERY STREET CAR.

# ARTIFICIAL PRODUCTION OF THE VOICE

## BY JACQUES BOYER

Dr Marage has succeeded in demonstrating, by numerous experiments, that the voice results from an intermittent vibration of the larynx and the air with in it, reinforced by the resonance of the mouth and other cavities situated above the larynx In a recent communication to the Paris Academy of Sciences, Dr Marage supplements this demonstration by proving that the larynx alone suffices for the production of these vibrations

In the first of these later experiments, performed on a living person Marage succeeded in nullifying the action of the buccal cavity by filling the mouth with 'steut,' a substance which is used by dentists for obtaining impressions of the mouth The steut which filled the mouth was traversed by a rigid tube which connected the larynx with the external atmosphere Although the resonant cavity of the mouth was thus suppressed, the five laryngian vowel sounds OO, O Ah, Ay, and Ee, were enunciated distinctly by the larynx alone

The investigation was continued by endeavoring to produce vocal sounds from a larynx detached from the body Muller had already experimented with the dead and isolated larynx, but the sounds which he obtained were quite different from those of the living larynx, and he stretched the vocal cords by applying forces much greater than the muscles of the larynx can exert These forces, which in some cases exceeded a weight of 2¼ pounds, would certainly have torn out the arytenoid cartilages of a living human larynx. Hence the conditions of Muller's experiments were abnormal

Marage employed, in his experiments, the larynx of the dog In order to spare the animal useless suffering, morphine was first administered hypodermically and, three hours later, the dog was put under the influence of chloroform, and the larynx, with five or six rings of the trachea, was excised. A rubber tube of the diameter of the trachea was then connected with the latter by means of a short tube of thin glass, so that a current of air could be forced through the extirpated larynx. The pressure of the air was measured with a very sensitive metallic manometer graduated in millimeters of water pressure. The compressed air was stored in a rubber bag similar to those which are employed for inhalations of oxygen, and was kept at the temperature of 98.6 deg. F. The muscles of the larynx were stimulated by the current of a small induction coil, which was energized by a storage battery, and the sounds

ARTIFICIAL PRODUCTION OF THE VOICE.

The left hand and right hand small engravings illustrate, respectively, the form assumed by the larynx in emitting a deep and a high note.

# WHAT SMOKELESS POWDER HAS MADE POSSIBLE.—I.

BY ROBERT G. SKERRETT

Except for saluting purposes, where smoke making is a factor in the ceremony, smokeless powder has supplanted the older propellants.

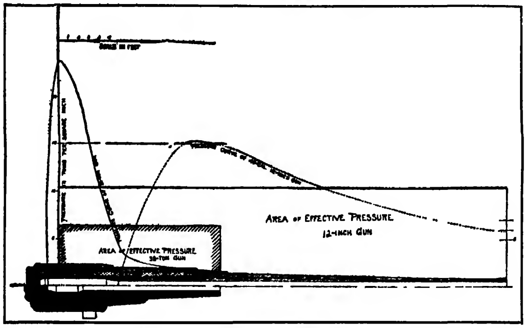
Our biggest battleships could not be given their present powerful armaments had not smokeless powder made it possible to add to the destructive force of our guns while calling for much less weight per unit of energy than formerly

Smokeless powder was first generally used in the French navy at the time of the devolpment of rapid fire guns to repel the swift torpedo boat The use of smoky gun powder in those weapons would have blanketed the defensive vessel in a cloud and have given a greater chance of success for the torpedo boat Thus, a military necessity demanded the change Once developed, however, smokeless powder became the stepping stone to a revolution in ordnance engineering This was due in the main to the differences between the physical actions of the old and the new propellents.

Black gun powder has a very dignified antiquity It is a mechanical mixture of saltpeter, charcoal, and sulphur Smokeless powder, on the other hand, is a chemical combination in which the atoms bear a different and a far more intimate relation to one another Common gun powder is a violent explosive and generates its gases with great suddenness Its grains, however, when burned in a confined space are only imperfectly consumed, and large volumes of smoke are generated. When used in guns the products of this combustion give about 40 per cent of propelling gases. These propulsive gases have the double burden of moving the shell and this inert mass of smoke and unburned grains.

Prior to our adoption of smokeless powder, the charge was about half the weight of the projectile—double the quantity of smokeless powder required to give the same ballistic results Black powder exerts a very great and disproportionate stress upon the breech of the gun. Thence toward the muzzle, the pressure drops suddenly—especially if the grains be small and the mass thus easily inflamed Our diagram shows graphically the quickness with which the highest pressures are developed and the rapid way in middle of these units so that as the consuming flame reduced the outer surface the burning area of the hole was increased, maintaining thus a relative balance of ignited surface and giving a more regular and gradual dealing with the briefest fractions of a second of time, but measurable intervals that mean everything to the ordnance engineer

Higher velocities and better ballistics followed But



| | Armstrong Gun. | U. S. Navy Gun |
|---|---|---|
| Caliber | 12.5 inches | 12.0 inches |
| Length of bore | 198 inches | 546 inches |
| Weight | 38 tons | 53.9 tons |
| Muzzle velocity (per second) | 1,400 feet | 2,900 feet |
| Maximum pressure | 25.8 tons | 15.8 tons |

| | Armstrong Gun | U. S. Navy Gun |
|---|---|---|
| Minimum pressure | 6 tons | 5.79 tons |
| Average pressure | 6.57 tons | 10.40 tons |
| Powder charge | 130 pounds | 365 pounds |
| Weight of projectile | 800 pounds | 870 pounds |

**Comparison of construction, powder pressures, etc., of the old Armstrong and the latest 12-inch navy gun.**

generation of gas. For a time, this answered But the gun grew, and the exposed surfaces of the greater powder charge required offered too large an initial burning area, and dangerously high and sudden pressures were produced at the breech of the weapon. there was actually more smoke than before, the bores of the guns were quickly fouled and there still remained a wasteful percentage of unburned grains Such was the state of the art in this country when we went to war with Spain

Weight of gun, 63 tons; Weight of shell, 1400 pounds; Powder charge, 365 pounds; Muzzle velocity, 2,600 feet per second; Muzzle energy, 65,687 foot-tons.

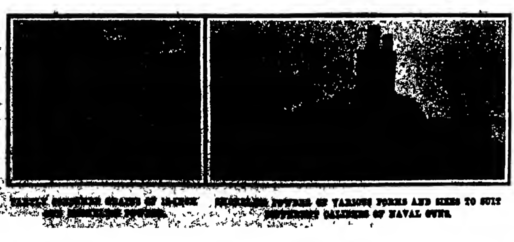
**THE NEW 14-INCH, 45-CALIBER GUN NOW UNDERGOING TEST FOR THE NAVY.**

which they fall—the average propulsive force being but a low percentage of the maximum power evolved It is this average pressure that sends the shot on its destructive errand, and the aim of the ordnance engineer is to have this reasonably high while lowering the crest of the curve of maximum energy

The first remedy tried was in the form of larger grains, so that, for a given weight of charge, the superficial area at once exposed to the flame should be reduced—the powder instead of going off with a single flash burned more slowly, and the propelling force was better distributed along the bore of the gun. This method led to the making of prismatic grains up to an inch and a half in diameter—regularly and carefully formed. Next, a hole was bored through the Besides this, a big percentage of the grain was blown out of the gun unconsumed Advance for a time was blocked until the powder makers evolved a "slow-burning" propellant by changing the proportions of some of the ingredients. The purpose of sulphur is to lower the ignition temperature of the powder, and by lessening this element inflammation was momentarily retarded By increasing the charcoal a greater percentage of moisture was added, and that served as a slowing-up agent in the general combustion of the mixture. The powder thus developed was called "cocoa" because of its color—the consequence of the undercharred charcoal used. In this country, we later called it "brown prismatic." The terms "quick" or "slow burning" are merely relative In either case we are

Smokeless powder has quite reversed the task of the ordnance engineer His aim now is to provide an explosive which can be made to suit the gun rather than to fashion the weapon to meet the violent vagaries of the older propellants Our present smokeless powder generates a relatively low regular, and progressive pressure from the instant of ignition up to the time the shot leaves the muzzle of the gun with its maximum velocity The curve of our big 12-inch rifles shows how much nearer the powder makers have come to solving the problem, but much patient experimenting has yet to be done before the ideal is measurably approached

The operative cycle of a shot moving along the bore of a gun is exactly opposite to that of a train of cars gaining full speed from a standstill In the latter case, the engineer knows that he would endanger his couplings—even if he did no other damage—if he opened wide the throttle at the instant of starting So he begins by just acquiring headway and then gradually increases the motive energy until the train has reached full speed—a matter of quite several minutes for a fast train and during a distance of a mile or two. The ordnance engineer, on the other hand, can give to his projectile only a flying start by suddenly applying a great and violent pressure, and enough of this propulsive force must follow the shell to the muzzle in order to give the desired maximum velocity This must be accomplished within a period of not more than one-hundredth of a second of time and in our biggest guns, while the shot travels a distance of not more than fifty feet A few figures will enable us to realize better the task set the ordnance engineer and



PARTLY CONSUMED GRAINS OF 12-INCH [illegible] SMOKELESS POWDER. SMOKELESS POWDER OF VARIOUS FORMS AND SIZES TO SUIT DIFFERENT CALIBERS OF NAVAL GUNS.

the part that smokeless powder plays in the result when measured by the power to strike an appalling blow. The shell leaves the muzzle of one of our latest 12-inch, 45-caliber rifles, with a velocity of 2 950 feet a second—33.52 miles a minute—and has a striking force at that instant equal to a blow of 52,632 foot tons. A fast express of 450 tons, thundering along at the rapid rate of 98.34 miles an hour to collision with a standing object, would be able to deal a blow of exactly corresponding magnitude. The gun's missile weighs but 870 pounds and the charge of powder 335 pounds—such is the power concentrated in our smokeless propellant, and yet so wonderfully regulated is the development of this stupendous energy that the weapon is actually less taxed than the older 12.5-inch rifle dealt with in the diagram, while the present-day gun has far more military value.

Referring to our diagram we see how far smokeless powder has made it possible to improve upon the performance of the Armstrong gun of the "eighties." That gun fired a shell of 820 pounds, used a charge of 130 pounds of black powder and gave to its shot a muzzle velocity of 1 400 feet a second. At the instant the shot left the gun it had a striking energy of 10,980 foot tons. To-day our big 12-inch rifles weighing but forty-odd per cent more than the older weapon, can send their 870-pound armor-piercing shell on an errand of destruction with an initial speed of nearly 3 000 feet a second—delivering at the muzzle a blow nearly five times as great as that of the Armstrong gun. The 38-ton gun, with a powder charge scarcely more than a third of that now used, developed the dangerous maximum pressure of 24 tons to the square inch in the powder chamber. Our big "twelves"—using 365 pounds of smokeless powder—have a maximum chamber pressure in service of not more than 16 tons. This means a reduction of stress upon the breech of the weapon of quite 33 per cent, and yet yielding an average propulsive pressure of something more than 60 per cent greater, all because the present powder burns slower and exerts its driving power for a longer period during the passage of the shell along the bore of the rifle. It is the difference between the shock of a single, sudden, violent impulse and the better-sustained push by which an object may be set in motion and accelerated.

Surely these are truly astonishing strides, and yet so unobtrusively have they been made from year to year that but few of us have realized their extent and their significance in strengthening our powers of defense and of retaliation. Such are the achievements of to-day. What may we not expect to-morrow?

(To be continued.)

## A NEW UNITED STATES NAVAL GUN OF GREAT POWER.

Our illustration of the new naval 14-inch gun cannot fail to excite widespread interest among those who are following the trend of development in the United States navy. The piece was constructed at the Midvale Works from plans of the Bureau of Ordnance, and received its finishing touches in the naval gun shops at Washington. It is now undergoing tests at the Indian Head Proving Ground which are giving much satisfaction to the officers of the Bureau.

There seems to be a growing conviction among some of the leading naval powers that, in view of the fact that future engagements will be fought at long ranges at which the remaining energy increases greatly with an increase in the size of the gun, future dreadnoughts will be armed with a piece of larger caliber than twelve inches. Great Britain is building, if she has not already completed, a 13½-inch gun, and our 14-inch piece has been designed and is now being tested, with a view to putting our navy in a position to arm future dreadnoughts entirely with the 14-inch if it should be deemed desirable to do so.

The new weapon, which will be 45 calibers in length (that is to say its length will be 45 times the bore), measures over all 53 feet 6¼ inches, and it weighs 63 tons. It fires a projectile of 1,400 pounds weight with a charge of 365 pounds of smokeless powder and the shell leaves the muzzle of the gun with a velocity of 2,600 feet per second and an energy of 65,687 foot-tons. It will be noticed that the velocity is 350 feet a second less than that of our latest 12-inch gun, but that because of the heavier shell the muzzle energy is greater. The lower velocity has the great advantage that the pressures and temperatures in the bore of the gun will be less and therefore the erosion will be reduced and the life of the gun before the rifling is so badly worn away as to destroy the accuracy will be considerably longer. The method of construction is generally similar to that shown in the accompanying article entitled "What Smokeless Powder Has Made Possible"; and, except that the powder pressures are lower, the curve of pressure from the powder chamber to the muzzle is approximately the same for the two pieces.

---

The telescope which is being installed in the Transvaal Observatory will be the second largest in the British Empire. It will be 35 feet long and have an aperture 26 inches in diameter.

## The Rockefeller Institute's Work on Infantile Paralysis.

BY JOHN B. HUBER, A.M., M.D.

The psychic machinery in our body is made up of two systems—the cerebro-spinal and the sympathetic, the latter does not here concern us. The cerebro-spinal system is made up of the brain, the spinal cord and the nerves, which are derived from the cord and extend thence to the muscles, the skin, and the uttermost tissues. The basis of this nervous system is the neurone, composed of a cell body (gray matter), and its dendrites or fibers (white matter) which emanate from the cell like the roots of a tree. The neurones are sensory and motor, and infantile paralysis is an affection of the motor neurone. The whole is like a telegraph system. The fibers (which make up the nerves) are the telegraph wires, the cell bodies (as grouped in ganglia) are the telegraph stations, communicating by their fibers with the extremities, with one another, and with the main office in the brain cortex.

The sensory ganglia in the spinal cord, to which sensations are telegraphed from the surface of the body, are in the posterior "horns", thence the sensations are transmitted to the brain cortex, from which in return commands are sent down through the motor ganglia, in the anterior horns of the spinal cord to the muscles working the affected area.

Infantile paralysis is known also to physicians as anterior poliomyelitis (*polios* gray, *myelis*, marrow—a term applied no doubt when the gray matter was erroneously supposed to be marrow, and *itis*, inflammation). So this disease is an inflammation of the anterior horns in the spinal cord—those parts of the cord which are concerned in muscular movements and development, and such a lesion means paralysis, atrophy or degeneration in the particular muscles innervated from the part of the cord involved.

Infantile paralysis is generally an acute disease, and by far the greatest sufferers from it are little children from one to five years of age. Apart from the pathos in this circumstance, we would infer (though not, of course conclusively) the infectious nature of this form of paralysis. For almost all the acute infections—measles, scarlet fever, whooping cough, and the like—are generally diseases of childhood, adults and the aged seldom contract them, if they have once contracted them in childhood, because the attack in infancy has conferred in most cases, lifelong immunity upon the individual. Another reason for inferring infectivity in poliomyelitis is its frequently epidemic character, as in the summer of 1907, when nearly the whole Atlantic seaboard was swept, and again in the summer of 1909, when the disease appeared in New York and spread widely throughout the United States and Europe.

In perhaps two-thirds of the cases that have been studied physicians have concluded them to be infectious, though they could not prove this, in the remaining one-third the disease has been attributed to falls, to antecedent maturing fevers, and to hemorrhages into the spinal blood vessels. In the light of our present knowledge, however, it is safe to consider that such falls fevers and hemorrhages have not been causative of the poliomyelitis but rather predisposing factors making the tissues concerned vulnerable to the essential or specific virus.

The motor neurones in this paralysis become smaller, then they degenerate, liquefy, and finally shrivel up, the fibers emanating from them degenerate and atrophy. This process may go on to complete destruction of these precious elements, or it may be arrested at any stage. If arrested early, repair may ensue and the cells and their fibers regain fairly well their normal condition and function. If, unfortunately, the inflammation goes on, the size and shape of the spinal cord at the points involved are contracted and changed, and in consequence of this the muscles concerned become paralyzed, atrophic, and incapable of their proper function. When recovery does take place these muscles are apt to remain small, perhaps throughout lifetime. These little patients suffer also retarded bone growth deformity of the joints involved sometimes lateral curvature of the spine, sluggish circulation, and impaired nutrition.

Such an illness begins suddenly with a high temperature and all the symptoms accompanying a fever; there is a pain in the back and limbs; suddenly there supervenes paralysis, generally in the leg muscles. A child may be put to bed seemingly quite healthy, and may in the early morning manifest these sufferings. The outlook is generally good as to life itself, yet the severity and fatality of the disease, as in all infections, fluctuate widely; and taking it all in all, poliomyelitis is sufficiently disastrous to give medical men much anxiety, as it should give the community in general grave concern.

As intimated, the infectious nature of poliomyelitis has been rather assumed than proved; it would now seem that complete demonstration of infectivity will presently be forthcoming. We may then entertain the confident hope of a preventive and immunizing agent against infantile paralysis akin to that which has practically eliminated smallpox from human experience. Early in 1909 two German experimenters, Landsteiner and Popper, successfully inoculated two monkeys with the spinal cords taken from two fatal human cases of poliomyelitis. In both the monkeys lesions of the spinal cord were on autopsy found similar to those in man.

In September of 1909 Dr. Simon Flexner and his colleague, Dr. Paul A. Lewis, of the Rockefeller Institute, in New York city, obtained the cords of two children that had unfortunately died of poliomyelitis, in which cords the anterior horns exhibited the characteristic gross and microscopic appearances. Transmission was then made to monkeys. After ether anesthesia inoculation was made in the brain of these simians through a small trephine opening. The injected material consisted first of emulsions in salt solution of the two human cords; and later of emulsions of the spinal cords of the monkeys that had developed paralysis after injection of the first emulsion, that from the human cords. The spinal cords in six series of monkeys thus inoculated showed without exception lesions similar to those of human poliomyelitis.

Now, a single successful inoculation with human virus resulting in experimental poliomyelitis could not establish the scientific case here set forth, because the result might have been due to a transferred toxic body, but in the experiments of Flexner and Lewis the transfer of the active agency of epidemic infantile paralysis was regularly successful. In one series of seven monkeys the first inoculation was of human virus, the other monkeys were successively inoculated each with the virus from the cord or the cortex of its predecessor, the disease regularly resulting. Hence, by these and other equally conclusive experiments, one cannot doubt the infectious nature of poliomyelitis.

Again, later injections were made, not only in the brain of monkeys but also into the abdominal cavity, the blood vessels, into nerve substance (as in the sciatic) of these animals. Nor "can it yet be affirmed that still other avenues of infection (as the skin, the organs of respiration or the digestive tract) do not exist, for the entrance of the virus into the central nervous system."

But now as to the nature of this virus which is responsible for infantile paralysis. It is at present invisible under the microscope. Flexner and Lewis after most exhaustive search, have found that it is neither a bacterium nor a protozoon, which parasites have been isolated as pathogenic of most of the infectious diseases. The virus of infantile paralysis—its infecting agent—is of the same nature as that of smallpox, it belongs to the class of the minute and filterable viruses that have thus far not been demonstrated with certainty. Nevertheless, although the smallpox virus still remains invisible to us, for a century past a vaccine has been evolved from it by which we have practically banished this dreadful disease from the face of the earth, there should then be no reason in science why a vaccine or an immunizing agent against poliomyelitis should not now in good time be forthcoming.

By the way, did the reader note in this paper the phrase "after ether anesthesia?" It means that the monkeys suffered no torture during these experiments, so beneficent in their trend for humankind. Let us congratulate ourselves that infantile paralysis is another added to the long list of dreadful diseases for which a remedy is being found through animal experimentation, which could otherwise never have been evolved.

## An Electro-pneumatic Conveyor System for Libraries.

An electro-pneumatic system is used in the Berlin royal library for carrying out the distribution of books to the readers. Upon this system the reader fills out a blank containing the name of the desired book, and upon this blank an employee writes an exact indication of the place where such volume is to be found. The bulletin is then sent by pneumatic tube to the central office. This office is directly connected by elevators with the different stories of the building. These elevators are of small size and are operated electrically on a push-button system. Besides, there is a large elevator running through all the floors for transporting persons and books. A set of pneumatic tubes also run from the central office to the different floors which contain the books. The employee of the central office who receives the reader's bulletin sends the same by pneumatic tube to the proper floor, and on this floor the attendants read the sheet and bring the desired books to the elevator which takes them to the central office. This latter office then sends the books to the point from which the bulletin was sent in the first place, either in the main reading room or any other of the rooms of the library.

### THE GYROSCOPE AS A CLOCK.

To the Editor of the SCIENTIFIC AMERICAN

In regard to Mr. Baker's item in the January 1st number relating to the gyroscope not maintaining its position relative to the earth, but relative to a fixed point in space, if this be true, the gyroscope, operated by a small motor and set on a balanced pivot, would make an excellent timepiece, although slightly different from those in present use, make only one revolution in 24 hours The clock would of course have to be set with the axis north and south, so the gyroscope would (apparently) rotate from west to east. It could also be geared so as to denote the minutes and seconds, and would be absolutely accurate, with the exception of the slight friction which would have the effect of slowing the clock a trifle

It occurs to me also that the same principle might be made use of in maintaining the position of astronomical telescopes, if the vibration could be overcome, instead of the mechanical, clockwork devices now in use.

To anyone who has the inclination to experiment in this way, a timepiece of this character would make an interesting toy, and could be very cheaply constructed An ordinary toy electric motor should serve the purpose of a gyroscope CARL OFSTHUN

Edmonton, Alberta.

### WHY DOES A WATCH-SPRING BREAK?

To the Editor of the SCIENTIFIC AMERICAN

Why does a watch spring break after being in use quite a while? If not strong enough, why did it not break at the very beginning?

Such is the question propounded by the Editors of the SCIENTIFIC AMERICAN

Let us suppose a strip of iron to be fastened at one end, the other end being free If we bend it a little and then let it go it will return to its place after vibrating a certain length of time It may do the same again and again, when we bend it more and more until finally after being bent beyond what is called the limit of elasticity, it will be permanently deformed Its molecules have then assumed a difficult position in regard to each other from that they had before

If we keep on bending it still more it will finally break in two at the point where the strain is greatest or where a defect may exist

Now let us try a good steel spring Here we find no deformation appreciable When we bend it beyond its strength, it snaps at once At least it appears to be so The probability is, however, that a permanent bending takes place first but at a point so near the breaking point that the difference escapes our observation entirely

Passing to the other extreme we will take a strip of lead There is then almost no elasticity, a very slight bending will deform the piece, but on the other hand, it will take a considerable amount of bending or twisting to break it

So much for the immediate effects of bending or otherwise straining any given material But now the question arises, what might be the effect of a strain not quite sufficient to produce an immediate deformation, but applied during a long time?

I can give here an example that I have often the occasion to verify Take a piece of tin and a piece of zinc (in sheet) of the same size, bend them to some extent and fasten them Two weeks later release them The tin will return immediately to its former shape while the zinc will remain bent just as it was fastened

Or take a piece of tar and put it on the table It will keep its shape, and even stand quite a pressure without deformation or breaking down Nevertheless in the course of a few days its molecules will have yielded to such an extent that the piece of tar has not even been able to stand its own weight, and has spread over the table

Now, what has taken place with the zinc or the tar undoubtedly occurs with the other materials within certain limits, at least it seems to me so The piece of iron kept bent near the point of immediate deformation, must in a sufficient time yield and be deformed The watch spring, or other steel spring, kept bent not quite enough to break must in course of time break up. The continued tension of the molecules must have a tendency to displace them, and finally causes them to yield

We have an immense amount of information as to the immediate deformation or breaking of materials of all kinds under stresses applied at once or during a short time, but only very little concerning the effects of stresses applied during a long time. Several suspension cables or bridge steel members have given way after years of service. The general opinion among engineers is that the breaking was due to the vibrations caused by the travel over the bridges. These vibrations caused the molecules of the steel or iron to assume a crystalline structure instead of the original fibrous disposition

It is said that a watch spring is more liable to break during warm than during cold weather I am very much tempted to question the correctness of that opinion However it may be so to some extent at least

In the first place, as a general rule the strength of all metals decreases with an increase of temperature Between the ordinary limits to which a watch is exposed, the difference is insignificant But it is not so as to the expansion of volume The diameter of the barrel changes but very little, but the spring, being very long, expands out of all proportion In fact the increase of length of the spring is about twenty five times the increase of size of the barrel

That is the equivalent of placing the spring in a smaller barrel and increasing its tension and liability of breakage in proportion ADRIAN GETAZ.

Knoxville, Tenn

### SAFETY IN MINES.

To the Editor of the SCIENTIFIC AMERICAN

In your issue of December 4th, 1909, in an editorial discussion of the Cherry mine disaster you state "the flames reached the dust-covered pine timbers of the structural work" This leads to a suggestion that the structural work in coal and other mines should not be made up of pine or other timber at all, but of iron or steel Also, from another part of your discussion I conclude that ventilating shafts should be distinct from the hoisting shafts.

In fact, the whole subject of protection to the miners should be studied out by scientific mining experts The duty to protect the workmen rests as moral duty on the owners and operators of the mines and this moral duty is in need of legal enforcement by appropriate statutes State and federal The men are clearly entitled to protection, and protection would in the long run pay in dollars as well as lives

The whole subject of protection from preventable disasters—and most of them are preventable as is generally discovered after the event—needs to be made the subject of expert scientific study The loss of life and limb due to accidents in mines, in railways and to burning factories theaters school houses and hotels is appallingly great, the more so when much of it, most of it, is clearly preventable But right here it must be emphasized that too much reliance is had on mechanical signal systems such as block signals on railways and the like No mechanical system can obviate the need of supplementary personal human vigilance There must be still the human watchman to supplement the mechanical system Mechanical systems have their advantages—the advantages of automatism But automatism needs the aid of human intelligence and vigilance There is too little value placed on human life - the lives of workmen, of travelers of the spectators at the play, of the children in the great crowded school houses The man who sees his loved ones start on a journey is likely never to see them again, or at best (or worst) their charred, almost unidentifiable remains Or if they live, it is to be maimed, disfigured cripples. Or the man himself may be stricken in his prime—the untimely victim of a lack of care or of undervaluation of human life Or the president of the railway system—as has happened more than once in the last decade—may himself become the victim of his own neglect and may ride to death in his palatial special

The whole matter of accidents is in a condition unworthy of the intelligence of the country For one thing, there is lack of constant inspection—eternal inspection, day and night There seems to be an unwarranted confidence in wood, iron and steel, a gratuitous assumption that accidents are not likely to happen The proper wiser assumption is that they are sure to happen unless forestalled They certainly do happen But somehow they do not seem to be taken into serious account The plans for running railways, mines, and factories leave the certainty of accidents too much out of consideration, as if they were mere "sports" of Nature, mere chances, whereas they are the certain and inevitable and hence preventable results of well known factors—factors of wear and tear, factors of growing structural weakness in timbers and steel, factors of over possible congruity of unfavorable circumstances, the incidental coming together of combustible elements etc

In hotels it must be assumed that fires are likely to happen at any or all times, and there is need of the eternal vigilance of a sufficient number of trained brains to keep the whole area of danger under intelligent surveillance Mechanical appliances should not be regarded as a substitute for these living inspectors but merely aids. For the automatic system has a canny, nnmechanical way of getting "out of fix" at the worst possible time Indeed it can be depended on to do this very thing. These observations apply to railways, mines, and factories It is not sufficient to have a jury determine whose negligence caused the accident or to say that it was due to some imperfection in the automatic signals Prevention is the thing Think what horrible deaths—deaths of scalding, burning, crushing, maiming—American men, women, children and babes are dying almost hourly The sickening scene is familiar—the 'unlooked for accident—the sending for the nearest village or town surgeons, the "carting away," the "shoveling up" of the mangled remains, the horrible identification of charred remains by some jewel or scrap of a shoe or fragment of apparel Prevention is the thing through expert scientific study and adequate inspection The subject is of enough importance to warrant it being taken up in the great universities and technical schools, so that men could be trained by proper study and practice to take charge of the important work of saving life by preventing accidents It would be a noble and useful work, if achieved—and it can be achieved Railroads or railways systems should have a department with a trained corps of men to cope with these conditions out of which accidents arise At its head a competent man, not to operate trains, but to remove the dangers of accidental death sure to arise when all are bent on running the trains on schedule (as now) and no one is thinking particularly of the human lives entrusted to the railways system, these dangers would be greatly minimized if the right steps are taken There is a railway west of the Mississippi River that has been operated for several decades, and it enjoys this unenviable distinction The road has never caused a single human death I have heard also of a steamship line that has never lost a passenger's life This shows what is possible If these conditions were general how much happier everybody would be E L. BLACKSHEAR,

Fellow American Association for the Advancement of Science

### The Current Supplement

The great bridge over the Red River in Indo-China is the subject of an article which opens the Current Supplement No 1779 Mr Richards explains some principles in design of friction clutches A new valve gear for gas engines is described and illustrated. An automobile chart has been invented by Mr Joseph J Jones which serves the functions of a mechanical sign post Briefly the invention is a revolving card which tells the driver or any one in a car exactly where he happens to be upon a road An article on the German "Dreadnoughts' of the 'Nassau' type is published A Leitermoser discusses the present state of physical chemistry in colloids Dr G Hudson Makuen writes on stammering and gives some suggestions as to modern methods of remedy J T Cunningham writes on transformations and migrations of eels Most of us have probably never heard of Nicole Oresme, yet he was the forerunner of Copernicus Prof Pierre Durham does credit to his work in an appreciative article A very exhaustive article on the Paris tunnels will be found in the SUPPLEMENT, an article of peculiar interest in view of the recent inundation of the French capital

The depth of the water in the middle of the Berlin-Stettin Canal will be 6 meters (19 84 feet), and the breadth at the surface in ordinary soil 33 meters (108 24 feet) In soft peaty ground it will be from 37 meters to 38 meters (121 4 to 124 6 feet) For a distance of 16 miles the bed and banks of the canal will have to be puddled with clay, the surface of the canal there being above the water level of the surrounding country At one point the canal crosses the valley of the river by an embankment provided with a culvert 160 meters in length The eleven locks for the descent into the Oder Valley are begun One of them has a fall of 9 meters (29 52 feet) The question of building a lift besides the series of locks has not yet been decided The 37 canal bridges are all to be built of steel

# CLEARING SNOW FROM RAILWAY TRACKS IN CANADA.

BY FRANK C. PERKINS.

The accompanying illustrations show the construction and operation of a novel cylinder snow plow designed and constructed in the Province of Ontario When the plow of this remarkable machine is forced into a drift or cut, the snow is lifted by the shovel, which is inclined upward and meets the expeller chambers, the snow gliding along until it comes in contact with the expellers the blades of which revolve at a high speed in an upward direction Engaging the snow the blades throw it upward and outward at a great velocity, delivering it to a distance of 50 or 60 feet on each side of the plow and making a clear cut, 11 feet in width and at a speed of 6 to 8 miles per hour in a cut 10 feet deep The snow is elevated and thrown at so great a distance from the track the possibility of the smallest quantity ever getting into the cut again is precluded The snow does not enter the expeller chambers, and it is stated that the maximum velocity of the expeller blade at the periphery is 5 654 feet

The accompanying illustrations are front and side views of this remarkable cylinder snow plow In one view the snow expellers are shewn in operation, in another a cut 12 feet deep is illustrated The reader will doubtless note the impression which wedge and apron leave on the snow The thin end projects only 20 inches ahead of the expeller

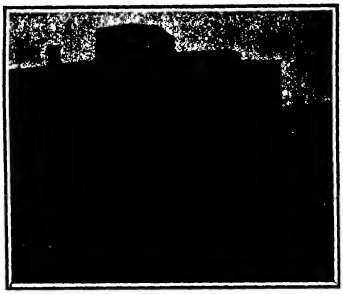
Other illustrations show the cleaned track in a ten foot cut, and the machinery within the plow car, including the boiler steam pipes and engine The expellers are directly connected with the engine shaft by means of two steel chain belts

It is stated that each of the steel chain belts driven by the steam engine of this plow is capable of driving the expellers at a moderate speed alone, so that should one belt be disabled the plow would still be able to work at a somewhat lower rate of speed

The plow body is of steel construction throughout, the box portion having the sides covered with wood like a box car The roof is of similar construction, which is fire and water proof A door is provided on each side in the middle of the car, the back end being left open for convenience in stoking the boiler A lookout is built at the front end of the car from which point the engineers can be signalled to

The front end of the car, entirely of steel, has three chambers, the two side ones being circular, open at the front and one side, in which the expellers revolve These are nine feet in diameter and three feet six inches wide Each expeller consists of a cast iron hub upon which are formed four spiral flanges, having a pitch of about fourteen feet Riveted to these flanges are four half inch steel plates or blades twenty two inches wide comprising a true helix upon the hub The expellers are mounted upon each end of the shaft and overhang the pedestals the shaft extending into the circular chambers. On the middle of the shaft, which is eight inches in diameter, is keyed the sprocket wheel, which is connected with a similar wheel on the shaft of the engine by the steel chains. These four parts constitute the drive gear The middle chamber opens to the interior of the car On the front is constructed the nose of the plow, consisting of steel plates projecting forward to the end of the apron or shovel It may be stated that the apron or shovel is attached to the bottom framing, the side plates, the interior web plates, and the expeller chambers, by steel angles and plates. This apron extends forward five feet beyond the center of the expellers. The nose and shovel, being firmly riveted together, present a rigid construction to engage the snow.

This powerful cylindrical snow plow has engines specially constructed The cylinders are sixteen inches diameter with eighteen inch stroke and work under a steam pressure of 160 pounds per square inch, the maximum speed being two hundred revolutions per minute They are capable of developing 750 I H.P. and are placed as near as possible to the expellers to shorten the drive chain The engines exhaust into the bottom of the smoke box of the boiler through a suitable nozzle similar to locomotive practice, creating a strong blast.



A view showing an expeller.

### Hardening of Soft Stone.

Mr A. Kubelka of Bushowitz in Moraira has discovered a process by means of which the softest sandstone or limestone can be made hard The process is the following First, the surface of the stone must be thoroughly cleaned, so as to expose the pores. Any oil or grease spots must be removed with benzine or with the alcohol flame Missing pieces must be filled up with cement mortar, using a 1 7 solution of waterglass for tempering After the stone is thoroughly dry, it is saturated with a solution of potash or soda waterglass In case of rain during or immediately after this operation, the stone must be again cleaned, dried, and saturated with the solution Then follows an impregnation with molten chloride of calcium After this impregnation rain will do no more harm, as on account of the reaction of the chloride of calcium upon the solution of waterglass, the pores of the stone will be filled with insoluble, hard silicate of lime, while the soluble silicate of lime will be decomposed and washed out by rain Another method of Kubelka's is to saturate the stone first with a solution of sulphate of alumina, in water, and when dry with a solution of potash waterglass. Sometimes a repetition of this process will be necessary to thoroughly fill all the pores of the stone. It is enough if the stone is saturated to a depth of about ½ inch. Whitish brush marks may be cleaned either by rubbing with a piece of the same stone, or by refacing the stone, or by brushing with steel brushes. Should the solution not impregnate the stone quick enough, it must be diluted with more water. The solution should be entirely absorbed by the stone in about one minute. Whatever is left over on the surface after this time should be wiped away with a rag, as the crystals formed by the evaporation of the water would make a rubbing and cleaning of the stone necessary A separate brush should be used for each solution, so that the reaction should begin in the pores of the stone. For larger surfaces atomizers or sprinklers may be used successfully.

Through these processes any soft limestone or sandstone may be made more compact and hard Their porousness and imperviousness will equal that of the hardest stone. After treatment they may be polished and cut The great advantages of the soft stones—cheapness of quarrying and cutting—remain, and they can receive afterward all the prominent qualities of the harder stones.

Mortar and concrete may also be hardened and compacted by these processes, so that they may be used with greater success in works calling for water-tightness, as water works, tanks, street pavements, sidewalks, artificial stone, cement blocks, etc

Monuments can also be protected by these processes from the influence of the weather

### Process of Removing Hair from Hides.

An article in the Ledertechnische Rundschau mentions, without describing in detail, a new process for the removal of hair from hides, in which the agents commonly employed for this purpose (lime, sodium sulphide, etc.) are replaced by "a suitable gas," which effects the removal of the hair in from two to eight hours. The process is said to be especially valuable for the preparation of colored leather and fine leather in general, as the product is of very uniform grain and free from the spots which are often produced by lime and sodium sulphide. The leather is also much closer, tougher, stronger, and more flexible than leather made by the usual methods. Hides treated by the new process may be tanned with bark, extract, or chrome alum The inventor, whose address may be obtained from the journal quoted, will furnish detailed information to persons interested.

### The Coming Aeronautic Show at Boston.

The first Aeronautic Show to be held in the United States without connection with any other exhibition, will open in Mechanics Building, Boston, Mass., on February 16th, and not on the 23rd, as announced in our last issue. This show will remain open one week. Sixteen full-sized aeroplanes have already been secured, and the exhibition promises to be a representative one as far as the heavier-than-air machines are concerned The manager can be addressed at 5 Park Square, Boston, by any experimenters having machines to exhibit.

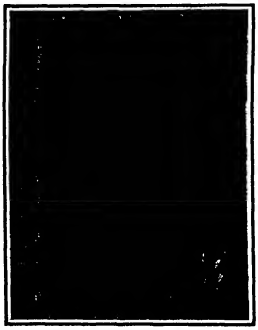
# BERNARD PALISSY, THE FAMOUS FRENCH POTTER, AND HIS WORKS

BY CHARLES A. BRASSLER

Bernard Palissy, whose statue by Barrias appropriately graces the court yard of the Ceramic Museum at Sèvres, is one of the most interesting figures in history

Born about 1510, near Agen, now in the department of Lot and Garonne, France, he was apprenticed early in life to a potter, and interested himself greatly in the technique of his calling, particularly in the possibilities of the various materials. He traveled in France and Germany, keeping this object in view and studying, for this purpose, geology and natural history, supporting himself in the meantime by working as a land surveyor About 1539, however, he settled at Saintes and here, while engaged in his calling, he began his systematic researches into the manufacture of pottery and the composition of enamels. It was here, he says in his book, "L'Art de la terre," "that without considering that I had no knowledge of argillaceous earths, I began my researches into enamels, like one who gropes in the dark."

An enameled cup of faience which came into his hands inspired him with the determination to discover a method of producing white enamel, and for nearly sixteen years, neglecting almost everything else, he devoted his time and attention to investigations and experiments in this direction. During this period, doubtless, he made the discoveries as to colorings, glazes, etc., that laid the foundation for his future success. His first attempts were unsuccessful, but he pursued his researches with unparalleled persistence and energy, sacrificing everything to what was then considered more or less of a chimera, and to what brought him no profit. He exhausted all his resources, and lacking fuel for the firing of his kilns, was reduced to the necessity of burning piece by piece his household furniture Ridiculed by his neighbors, bitterly reproached by his wife and tormented by the cries of his hungry children, he nevertheless persevered until finally, when reduced to the last desperate extremities, success rewarded his efforts.



Portrait of Palissy. From an old French miniature on vellum at Cluny.

Unlike most of the investigators and experimentalists of his time, Palissy had conducted his labors systematically, and when he attained his object, he was able to repeat his work and obtain the same results A few vessels, ornamented with life-like representations of reptiles, insects and small animals and colored true to nature, were a revelation to the ceramists of those times and brought prices that soon enabled him to forget the hardships through which he had fought his way to success. He continued and perfected his researches and soon became famous, winning favor with the nobility and royalty, in the embellishment of whose palaces his genius was chiefly employed This friendship stood him in good stead at the time of the massacre of St Bartholomew, when the powerful protection of Queen Catherine and Anne de Montmorency, wife of the constable, saved him from the fate that befell so many of his fellow Huguenots, for Palissy had embraced the reformed faith

A man of studious habits and keen intelligence Palissy was among the earliest of French scientists to substitute for the fables and fanciful theories of so-called philosophers, hard facts, that were capable of practical demonstration In 1575 he commenced the delivery of a course of lectures on natural history and physics, in which he gave a correct account of the origin of springs, the formation of stones and fossil shells, and advanced theories as to the best methods of purifying water, the use of marl as fer

## THE HEAVENS IN FEBRUARY, 1910

BY HENRY NORRIS RUSSELL, PH. D.

FIRST among the astronomical discoveries of 1910 is that of a brilliant comet reported from South Africa on the 17th of January

At that time it was but five degrees south of the sun, but it was so bright that it was visible in full daylight to the unaided eye, and observations of its spectrum, made next day at the Lick Observatory, showed the sodium lines bright on a continuous background—thus proving that the comet was very hot and self luminous.

This doubtless means that it was then very near the sun, and strongly heated by its radiation

From the scanty information which is yet available it appears that the comet is moving rapidly northeastward and diminishing in brightness. Its orbit has been computed and ephemeris will be found on page 123 of this issue It is probable that it will be visible for a few weeks in the evening sky, just after sunset, and almost directly above the point where the sun disappears. It is, however, quite possible that it may lose so much in brightness, as it retreats from the sun that it will not be very conspicuous On the other hand, it may be a fine object, and the evening skies will be well worth watching especially about the beginning of February when moonlight no longer drowns out faint objects.

Halley's comet is still visible in the evening sky and is very slowly increasing in brightness, but it will probably be too faint for the naked eye, though perhaps visible in a field glass.

It will fortunately be easy to locate Just north of the planet Saturn are three stars of the fourth magnitude, in an east and west line On February 5th the comet will be about 50 min of arc (or, roughly, one and a half times the moon's diameter) north of the middle one of these stars, and on the 17th it will be about the same distance north of the westernmost of the three By following this line of motion it can easily be found at any time

By the end of the month it will be pretty low in the west at sunset, and soon after it will vanish in the twilight, to reappear, much brighter, in the morning sky in April

While the appearance of these comets is exciting so much interest, a notable advance has been made in the explanation of these phenomena. Observations of the spectra of the last two bright comets (Daniel s and Morehouse s) showed that the light of the tail consisted almost entirely of bright bands, given out by some luminous gas. But at that time no gas was known which gave just these bands. Very recently Mr Fowler of South Kensington, England, has found that a vacuum tube, containing small quantities of nitrogen, and of carbon compounds (excited electrically so as to glow), shows a spectrum exactly like that of the comet's tails, provided the pressure of the gas is made exceedingly small

As the pressure and density of the gas in a comet's tail must be almost incalculably less than in any vacuum which we can produce by mechanical means, this gives us a satisfactory explanation of the observations The luminous particles though so thinly distributed through space, are molecules of familiar gases, and one of the mysteries which surround comets has been cleared away

### THE HEAVENS

The splendid and familiar winter constellations are now seen in all their glory

Due south and about half way up the sky is Orion The very bright star below him to the left is Sirius. West of this, directly below Orion, are the small groups of the Hare and the Dove. Far below the latter, on the southern horizon, those who live south of Virginia or Missouri can see a star of exceptional brightness. This is Canopus, the principal star of the great constellation Argo, and, next to Sirius, the brightest in the heavens. This star's brightness might make us anticipate that, like Sirius, it might be a near neighbor of ours in space, but repeated and careful observations show that this is not so Its distance is too great to measure accurately, but it is at least ten times as far off as Sirius, and probably much farther from us. Canopus must therefore be really a most magnificent luminary, exceeding our sun at least a thousand fold in brightness.

To the left of Orion and Taurus are Canis Minor and Gemini, and right overhead is Auriga, with the bright star Capella. In the southwest there is nothing of much interest, but in the west we see two bright objects, one above the other, not marked on the map These are the planets, Mars and Saturn, whose motion among the stars makes it impossible to put them in our permanent maps of the heavens Mars is higher up than Saturn, and is redder in color

In the northwest we see Andromeda and Cassiopeia, and above them Perseus. This is another of the constellations which bears no real resemblance to anything in particular, but with the aid of the drawing in our initial it is possible to see how the ancients found here the figure of the hero carrying the head of the Gorgon Medusa, which is marked by the bright star Algol

The bright spot in the Milky Way, between Perseus and Cassiopeia, is a splendid star cluster, showing well in the smallest telescopes.

To see how the northern constellations appear in the sky, we must turn our map upside down, so that the words "Northern Horizon" are at the bottom. It will then appear that Cepheus is below the Pole, on the left. The Little Bear hangs by its tail from the Polestar. The Dragon is below, with his head out of sight and only his tail showing. The Great Bear is climbing up the heavens to the eastward, and is already high In the east is Leo, pretty well up, and above is Cancer, with the star cluster Praesepe. Farther to the right is Hydra—an immense constellation, whose head is already high while its tail will continue to drag itself into sight for three hours longer.

### THE PLANETS.

Mercury is morning star throughout the month, but is unfavorably placed south of the sun He may be best seen about the 20th, when he rises about 5·40 A. M

Venus is evening star until the 12th, when she passes between us and the sun and becomes a morning star. At the beginning of the month she is easily visible in the evening, setting more than an hour and a half later than the sun, and at its end she is similarly conspicuous in the morning skies.

During the middle of February she will be invisible to the naked eye, but as she passes almost 8 degrees north of the sun, she should be observable telescopically, in full daylight, as a thin crescent, all through this time.

Mars is evening star in Aries, remaining in sight till nearly midnight.

Jupiter is in Virgo, rising about 10 30 P M. at the beginning of the month, and 8 30 at its close.

Saturn is evening star in Pisces, setting about 10 P M in the middle of the month.

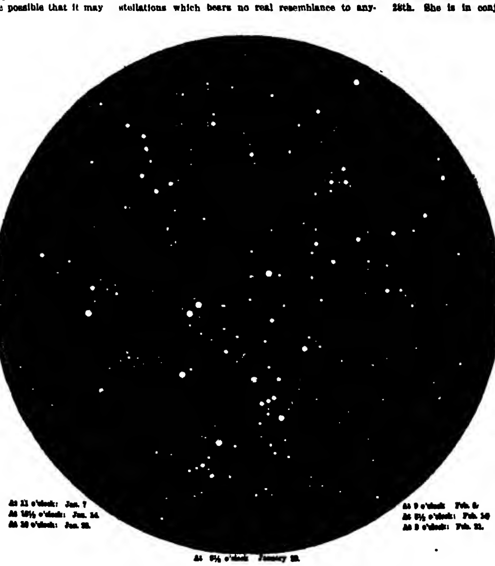
Uranus rises only about 1½ hours before the sun, and is unobservable.

Neptune is in Gemini, observable all the evening, but only with a good-sized telescope.

### THE MOON

Last quarter occurs at 6 A. M on the 2nd, new moon at 8 P M on the 9th, first quarter at 10 P M on the 17th, and full moon at 3 P M on the 23rd. The moon is nearest us on the 12th, and farthest away on the 28th. She is in conjunction with Uranus and Mercury on the 7th Venus on the 9th, Saturn on the 13th, Mars on the 15th, Neptune on the 20th, and Jupiter on the 27th

Princeton University Observatory



NIGHT SKY: JANUARY AND FEBRUARY

### The Library of the Assyrian King, Sardanapalus.

During the interval of the past fifty years twenty thousand stone tablets, approximately, of the library of the Assyrian king, Sardanapalus, were found in the course of excavations among the ruins of Nineveh and taken to London The texts written on them, which are related to one another apparently, are now published in their original cuneiform script by the British Museum in serial collections Various savants of the whole world have therefore an opportunity for further investigation of the texts of their special province, for every kind of text in cuneiform script presents its own particular difficulties to the translator and commentator In the fourteenth collection, or volume of the work are assembled those tablets of the king's library which regard chiefly the objects of the three natural kingdoms. Obviously many of these lists were prepared for purposes of medication.

For this reason a prominent physician, Baron Oefele, assisted by noted scholars in cuneiform script among them Prof Zimmern of Leipzig, began to examine this collection with a degree of zeal that has become quite prolific. Apart from the many lists which mention minerals, the numerous lists of animals are mostly of a uniform kind The names of animals are arranged in two columns, the same names being given in the first column in Sumerian and in the second column in Accadian, that is, in Babylonian Still far more interesting than the zoological lists are the botanical lists, of which there is a great number, and which give the most various directions to acquaint the aspiring physician with the effect and use of hundreds of medicinal plants. This fact may suffice to show that among the old Babylonians the knowledge of the natural sciences was already far greater than among their successors, the Greeks and Romans, whose names of animals and plants, it is manifest, have been derived partly from the Babylonian language.

---

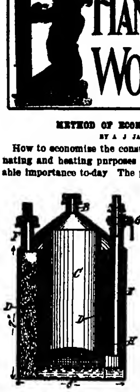
The shortest track for steamers from Panama to Yokohama, Shanghai, and Hongkong passes in close proximity to San Lucas Bay, near Cape San Lucas, at the southern end of Lower California, and to the ports of Manzanillo and Acapulco on the mainland of Mexico. Perhaps Manzanillo should be regarded as the closest port.

# HANDY MAN'S WORKSHOP

## METHOD OF ECONOMIZING GAS.

BY A. J. JARMAN

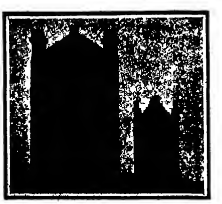
How to economize the consumption of gas for illuminating and heating purposes is a question of considerable importance to-day. The price charged for coal gas at the present time in many towns and cities is so high as to prevent its use for cooking purposes. Only by exercising the utmost economy in using only just enough to cook the small quantity of food required does the use of gas for cooking become advantageous under such conditions.



SECTION OF THE GAS ECONOMIZING APPARATUS.

By means of a simple apparatus the heating qualities of the gas can be improved so as to reduce cooking expenses and the cost of lighting as well, for in Welsbach and kindred lamps it is the heat of the burning gas that renders the mantle brilliantly incandescent. Moreover the lighting qualities of the gas are greatly improved as well. The following apparatus, which was first made by the writer in 1872, has been put to the test in hundreds of cases and has proved its efficiency in every instance. Any man who is handy in the use of metal working tools can make one and fit it to suit his gas supply by attaching it to the supply pipe after the gas has passed the meter, the gas then belongs to the consumer, it being the property of the gas company before it passes the meter.

The apparatus here described is suitable for a ten light meter, with all the fittings for lighting, heating and cooking. It consists of a closed tin cylinder *A* six inches in diameter and seven inches high without the conical top. Within this vessel is placed another cylinder made of galvanized wire netting, with a half inch mesh the diameter being four inches and height seven inches. This wire cylinder is placed within the tin case, having a one-inch space all round. Within this space clean, white cotton waste is packed. A tin cylinder *C* six and a half inches long and three and one-half inches diameter is soldered all round to the cone top of the cylinder *A* and is provided with a perforated bottom to allow the hydrocarbon with which the economizer is to be charged to run through and saturate the cotton waste *D*. The cylinder *C* acts as a spreader, causing the gas which enters by way of pipe *E* to contact in a thin layer with the cotton waste held by the galvanized wire cylinder and then pass out through pipe *F*. The apparatus is charged with benzine, gasoline, or a similar volatile hydrocarbon capable of being taken up by the nonilluminating constituents of coal gas, such as hydrogen, marsh gas or carbonic oxide. At *G* is a suitable brass stop-cock which enables one to turn off the gas when charging



A 100-LIGHT AND A 10-LIGHT GAS ECONOMIZER.

the apparatus with gasoline. The brass cap at *B* must have a disk of pliable leather fitted in the interior so that it becomes perfectly gas-tight when screwed down. It is necessary to make a hole in the supply pipe *E* at *H* so that in case the gasoline should cover the bottom of the inlet pipe this would prevent any flickering of the light due to bubbling of the gas through the liquid.

The charging of the apparatus must be carried out in daylight, and it should be fitted near a window where daylight is admitted, for a lighted match, candle or lamp must not be used. With these simple precautions the apparatus is perfectly safe. The cone top must be perfectly soldered where the tin cylinder meets, and all the brass connections attached to the inlet and outlet pipes must also be perfectly soldered. India rubber piping or connectors must not be used; soldered connections, metal piping and screened brass connectors alone must be used. When the economizer is fitted and charged with about three pints of gasoline it will be found that the intensity of light from an ordinary naked burner will be vastly improved.

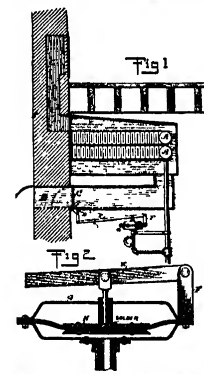
It has been found that half a gallon of benzine will take the place of 500 cubic feet for direct illumination in this apparatus.

The cotton waste in the economizer must be packed moderately tight. If packed too loose it will sink and give less surface for the gas to reach the gasoline. Be sure and mark the outer end of the inlet pipe *IN*. This will prevent any mistake when installing the device.

## REGULATOR FOR INDIRECT AND DIRECT-INDIRECT STEAM HEATING

BY R. A. JOHNS

Every indirect and direct-indirect steam heater should have some kind of a regulator so as to shut off the air supply when there is no heat in the radiator, otherwise, especially at night when the steam pressure goes down and the air box remains open with the



REGULATOR FOR INDIRECT STEAM HEATING

cold wind blowing directly into it, it will soon cool off the house.

The accompanying illustrations show a very simple way to make such a regulator. Fig. 1 shows the general arrangement of an indirect heating radiator, and Fig. 2 shows in detail the regulator.

The radiator *A* is inclosed in a box in the usual way taking its air from the outside through the passage *B* and having a shutter or damper *C* mounted to turn in suitable bearings on a shaft. The latter has a small bell crank *D* secured to its outer end which through a link is connected to a lever *E*. The lever *E* is pivoted in suitable brackets *F* fastened to the regulator *G*. The regulator can be made of two small frying pans or skillets say about 6 inches in diameter. A part of the conical rim is bent outward forming flanges for bolting the same together. The bending is done very easily. Place the skillet over the edge of an iron block, and with a flat peen hammer stretch the edge, say about ⅜ inch all around. To the lower head, rivet a small floor flange, which will serve for connection with the steampipe from the boiler. In the center of the upper head a hole is made large enough to receive a half inch nipple. To the lever is fastened a short rod which passes down through this nipple to the diaphragm *H*.

The diaphragm is made of sheet rubber, say 3/16 inch thick with one or more layers of duck in it. To the top and bottom disks of iron with beveled edges about ⅛ inch thick are riveted. To the upper disk is soldered a half inch nipple or piece of pipe, serving as a guide. The whole is now placed between the two heads of the regulator and bolted together very closely.

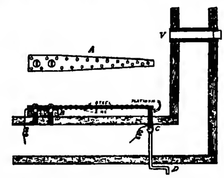
To the lower head is fastened the usual siphon pipe to prevent the steam from entering the regulator. As the steam pressure rises it will force the diaphragm upward, thereby opening the shutter *C* in the air passage *B*, permitting the cold air to pass under and through the bank of radiators, thereby heating them thence up through the register into the room and will keep it open until the steam pressure goes down. The weight of the arm *E* will then close the shutter permitting no more air to pass until again opened by the steam pressure. A weight may be attached to this lever, so as to close the shutter more effectually.

## THERMOSTATIC ALARM FOR HOUSE HEATERS

BY F. F. ALLEN

The accompanying diagram shows how a simple alarm for house heaters can be made.

The object of this alarm is to give warning when the furnace is overheated and needs attention, or when the fire is nearly out and needs more coal. A thermostatic bar *A* 1½ inches by 1/16-inch is made of copper



THERMOSTATIC ALARM FOR HOUSE HEATERS

and iron riveted together very closely and fastened at one end are brackets *B* which are secured to a suitable base *H*. The free end of the bar *A* moves between two contact points *D* made of ordinary screw-eyes. These are screwed into posts *C* made of ½ inch dowel and secured to the base *H*.

The whole is fastened in an inverted position over the furnace or other place where there is danger of overheating. After the contact points are adjusted to close the circuit at the proper temperature they are connected up to an electric bell and battery as indicated in the drawing.

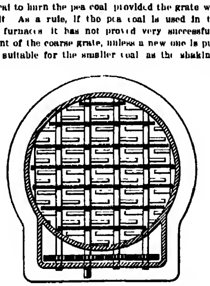
A switch is placed in the circuit at some convenient point. It will now be seen that when the thermostatic bar *B* moves to either side according to the temperature and makes connections with contact points *D* the bell *E* will ring. When the apparatus gives the necessary alarm the switch must be turned off until the trouble is remedied.

## ADAPTING A GRATE FOR SMALL COAL.

BY J. A. BERGSTROM

The grates in the ordinary house heating furnaces are regulated and made for the best and most suitable size of coal to be used in each particular case. That is to say in a large hot-air furnace where egg coal is most suitable, a very coarse and open grate is provided but in a smaller furnace where smaller coal is to be used, a much closer grate is furnished.

In some localities where pea coal is much cheaper than egg, stove or nut it would perhaps be more economical to burn the pea coal provided the grate would permit. As a rule, if the pea coal is used in these large furnaces it has not proved very successful on account of the coarse grate, unless a new one is put in more suitable for the smaller coal as the shaking of



GRATE ADAPTED FOR BURNING SMALL COAL.

the old grate will cause the whole fire to dump into the ash pit.

To overcome this the writer has tried several methods and has come to the conclusion that the best is that shown in the accompanying illustration.

The grate is an ordinary rocking finger grate. Between every or every other finger (which will depend upon the kind of grate and also of the size of coal to

be used) is placed across the entire grate a piece of say ½ inch pipe or bar. These pipes or bars rest on the grate bars and are not affected by the rocking of the grate. As the ashes accumulate on top of these bars they have a tendency to keep them in place and will prevent them from moving or burning.

There should always be a layer of an inch or two of ashes on any grate. Care should be taken not to shake the grate too much, as a great deal of live coal will fall through and sometimes start to burn in the ash pit, thereby warping and destroying the grate bars.

The writer has used some old pipes and grate bars for a number of years and to-day they are as good as new. Some years ago, during the coal famine, a great deal of bituminous coal was burned with perfect success. It is best when starting a new fire to clean out the ash pit, and if any live coals fall through they may be shoveled up on the fire again until enough ashes are formed to prevent them from falling through.

## HOW TO BURN COAL ECONOMICALLY

BY W. B. ALLEN

The accompanying illustrations show how in a very simple way the gases in an ordinary furnace may be consumed and burned, thereby giving off a more uniform heat and maintaining an even temperature throughout the house continuously night and day. It will effect a saving on the coal bin and produce more heat besides.

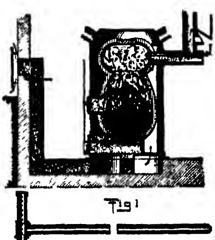
The fire in a stove or furnace is simply the result of a chemical union of the carbon properties of the fuel, both solid and gaseous, with the oxygen of the air.

By the complete combustion of one pound of coal 14,600 heat units are given off, but by the incomplete combustion of one pound of coal, as burned in the great majority of domestic heaters, only about 4,000 to 5,000 heat units are produced and the balance of the heat passes away up the chimney, a rich combustible gas that should have burned.

To obtain the highest efficiency from coal it must be burned with the least possible supply of air consistent with perfect combustion, as an excess of air carries the heat of the fuel into the chimney and a certain mixture of air from below the grate will cause an explosion in the smoke pipe, blowing the fire door open and filling the cellar with spent gases.

Nearly every furnace discharges so-called "coal gas" which is due either to poor draft or a defective furnace, or an improper adjustment of the dampers. As the odor is so noticeable, the difficulty is soon remedied. Every furnace, however, is constantly discharging more or less carbon monoxide gas, which is perfectly odorless and is a very energetic poison, as the result of imperfect combustion.

Ordinarily the domestic user of coal roasts out the gas, opens the dampers and drives it up the chimney and then proceeds to burn the coke, which is only about one-half of the heat value of the coal, besides it is not alone the heat that escapes up the chimney, but the rich combustible gas that passes away unconsumed. This gas when burned produces a uniformly



ARRANGEMENT FOR BURNING THE GASES OF THE COAL.

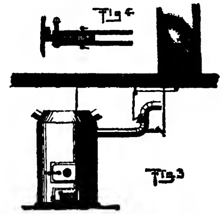
higher temperature than the coal itself, which may burn at varying temperatures, even so low as to produce but little heat.

The clinkers that form in the furnace are the result of an excessive draft below the grate.

To accomplish the mixing of the hot gases and air the air must be heated to the same temperature.

The most common domestic heating furnace is the hot-air furnace. This is simply an improved stove inclosed in a sheet iron or brick casing. The furnace heats the air within this inclosure to a high temperature and therefore rises to the rooms above through tin pipes. To keep this current of hot air rising, a "cold-air box" connects the lower part of the furnace with the outside air and is regulated with a damper. This cold-air box should always be kept open as much as possible and never entirely closed while there is fire in the furnace, as the furnace will become overheated and may be injured.

Fig. 1 shows how the common hot-air furnace may be adapted to burn the gas of the coal. A small pipe, say 1 inch or 1¼ inch, is inserted through the upper part of the smoke pipe (as the gases here are the hottest), terminating in close proximity to the smoke collar just inside of the radiator of the stove. The inner end may be fitted with a suitable spreader, such as shown in detail in Fig. 2. The cross pipes have a number of 3/16-inch holes drilled in the lower side, or



HAND METHOD OF REGULATING THE DAMPERS.

facing downward. The outer end of the pipe is fitted with some kind of a damper to regulate the supply of air. As the cold air passes through this pipe it becomes heated and at its delivery end is of the same temperature as the gases, but as the specific gravity of this heated air is much greater than that of the gases in the furnace, it drops down and mixes with the gases, forming a combustible mixture which now burns with a blue flame, just as in an ordinary gas stove. If a small piece of mica is inserted into the fire door this burning may be observed. It is a very interesting phenomenon.

In order to make the system a success the fire pot must be in perfect condition, that is to say, in a hot air furnace there should be no communication between the fire pot and the air chamber, no cracks and no loose joints. The fire door should be as air-tight as possible. This may be made tight in the following manner. First, file and remove all rust at the edge of the door until a metallic surface appears, then cut a narrow strip of asbestos and soak in salt water, after which place it around the door and it will adhere. Put a litle oil on the door frame and close the door. The asbestos will then fill up any opening and bake very hard on the door.

If everything below the grate were absolutely air tight no combustion would take place, but as all furnaces leak more or less this leakage is enough to support combustion in ordinary weather. In extremely cold weather, however, the slide in the ash pit door may be opened a little, so as to furnish a little more air.

A damper is attached to the smoke pipe above the air pipe, so that when open it will not cool off the air pipe.

A fire is built in the furnace the ordinary way, keep the air damper closed until a good fire is obtained, then put on some coal and keep the lower damper open for a few minutes, after which close all drafts and open the air damper, regulate the same according to the heat required, that is to say, more heat, more air. Through the before-mentioned mica window observe the results. All the gases in the furnace will, however, not burn, as some are bound to escape unconsumed.

There is more economy in running a large, slow fire all day long than a hot one at intervals. Therefore it is best to coal the fire twice a day, in the morning and at night, and regulate it so that the fire burns with an even temperature. It will keep the house at a uniform temperature night and day.

When the furnace has been cooled for the day or the night the dampers may be controlled from any room above by simply raising or lowering a lever connected with wires running over pulleys to the various dampers, thereby saving many a step. This is shown in Fig. 3, a sectional plan of the levers is shown in Fig. 4.

In ordinary weather the fire should only be shaken once a day, preferably in the morning, but in very mild weather twice a week will suffice. Only shake until the first red coal comes down. In furnaces with very strong drafts shake but very little, as the layer of ashes on top of the grate will help check the draft. If the fire is very low stick a few pieces of kindling wood into the fire. This will heat up the smoke pipe. The ash-pit door may also be opened until the fire is drawn up, then regulate as before described.

With this arrangement in good working order every particle of coal will burn to an ash. The slate in the coal, of course, will not burn.

This applies to all three heating systems in domestic use, namely, hot air, hot water, and steam, as it only takes care of the fire.

In hot-air heating, in addition to regulating the fire, the cold-air box must be regulated. This box generally terminates outside the building under a porch. It has always been a source of annoyance because of changes in the direction of the wind. Sometimes the wind will blow directly into it and cool off the house, but when the wind is in another direction it will suck the hot air out from the furnace into the atmosphere. To overcome this a shield is placed in front of the box, say 8 inches from the building, overlapping about 12 to 18 inches all around. Then it will be impossible for the wind to interfere with the regulation of the air, which is generally done in the cellar with a damper or shutter.

The pipes in the cellar leading to the registers should be kept clean, also the registers. Avoid putting any wire netting to catch articles dropped thereon, as it will catch more dirt than anything else, sometimes clogging up the meshes completely, forming an excellent breeding place for bacteria.

The water pan should be connected with the water supply, controlled by a float valve. This insures an even water level in the furnace.

In steam heating plants the boiler and radiators should be large enough to keep the house at a temperature of 70 deg. in zero weather with one pound of steam, as this will take a great deal less coal than when the boiler and radiators are too small, and require a steam pressure of 10 to 20 pounds.

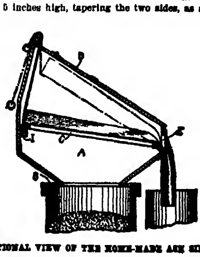
In houses where the draft is good one day and poor the next, despite favorable winds, the fault is with the chimney. It should be built higher. This is a great deal cheaper and better than to put an unsightly cap on it.

## HOME-MADE ASH SIFTER.

BY J. A. BROPHY

A dustless ash sifter can be made at a very small expenditure of money by following the lines of the accompanying drawing. Make a box *A* shaped as shown about 2 feet high, 2 feet long, and 10 inches high at its lowest part. The box should be of such a width as to fit a square hole in a base board *B*. Make the base board square to fit over top of an ash can and cut a square hole in the base board of such a size as to be entirely within the diameter of ash can. Nail the base board to the bottom of the box.

Then make a frame *C* of 1 inch wide stock, 1 inch narrower than the inside width of box and 1 inch shorter than the inside length of the box. Bore a ½-inch hole in the center of one end of this frame and cover the frame with ½-inch mesh galvanized netting. Inclose three sides of this frame with thin board about 5 inches high, tapering the two sides, as shown,



SECTIONAL VIEW OF THE HOME-MADE ASH SIFTER.

and leaving the discharge end open, which should be hinged to front end of box with two 2 by 2-inch hinges. Put a piece of rope through a hole in the upper end of frame and fasten it on top so that it will not pull out.

The box is now ready for the top which has a hinged door *D*, as shown. On top of box place a pulley and run the rope through the hole in the top of the box and over the pulley wheel. The end of the rope may have a large ring attached to it as shown.

This arrangement will allow the sifting frame to be swung up and down, jarring the frame every time it strikes the block *I* fastened to rear of the box.

Over the opening in front of box fasten a bag-shaped cloth to guide the clinkers to a suitable receptacle and prevent dust from rising.

This sifter has proved very clean and does not require a second shoveling of sifted ashes.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

BUTTON.—N Twery, Hillsboro, N D This invention refers particularly to means of attaching buttons to garments and the like The object is to produce a button having a resilient or extensible shank of improved construction, which will yield or give under strain so as to relieve the strain to which the attaching stitches or cord is subjected.

### Electrical Devices.

SPARKING DEVICE.—I W Gilks, New Bedford, and C W Torry, Fairhaven, Mass. An object of this improvement is to provide a circuit breaker on an induction coil which will give one large spark instead of a succession of sparks, such as those produced by the ordinary form of vibrator Means are provided by which the core of the coil may be thoroughly magnetized before the break occurs.

### Of Interest to Farmers.

COVERED BARN DOOR TRACK AND HANGER.—E F Monnier, Coggon, Iowa The principal objects which the present invention has in view are: to provide a device for hanging sliding doors, which is fully protected from rain and snow, and to provide a device which is simplified in construction and arranged to permit the installation thereof by an unskilled person

HAY LOADER.—J A Johnson, Wasco, Ill The mechanism carries the hay from the ground to an elevated point and deposits it into a suitable vehicle The elevation of the material handled is conducted so that the tailings are not carried over and deposited between the vehicle being loaded and the loader

HEATER FOR THRESHING MACHINES.—J F Hixes Strawberry Point and G Fetler, Osborne, Iowa In the present patent the object in view is the provision of a heater frame, simple in construction while efficient for the purpose and which may be easily removed and replaced, and whose stroke may be adjusted in length independently of the other frames in the series.

### Of General Interest.

PICKPOCKET DETECTOR. M. Wald, New York, N Y This invention relates to an improvement in garments, and particularly to a new and improved pocket, which is formed with a deep true pocket, and a shallow false pocket and detecting the intrusion of a pickpocket's hand therein. The pocket may be attached to any part of any garment

DREDGING SLEEVE.—W P Suod, Oakland, Cal The object of the invention is to produce a sleeve having a protecting wall or coat of mail extending continuously around the axis of the sleeve and protecting it against injury from sand, gravel and small rocks, but at the same time permitting perfect freedom in flexing or doubling the tube

BASKET HOLDER.—U S. Paine and A. D Paine, Winslow Maine The purpose of the invention is to provide novel features of construction for a basket holder, particularly adapted for the reliable holding of a plurality of berry baskets or other small fruit baskets at the front of the gatherer, so that berries may be conveniently removed from the plants or bushes and deposited in the baskets, both hands of a person being free for the gathering operation When the baskets are filled with berries, they may be removed by sliding them from engagement, and empty baskets may be placed in position

HYDRAULIC AIR COMPRESSOR.—J W Neal, Kelis Hawaii The invention provides a new hydraulic air compressor, arranged to utilize the force of the pumped water to compress the air isothermally in a very simple and efficient manner It relates to compressors more especially designed for use with wave motors, such, for instance, as shown and described in Letters Patent of the U S., twice formerly granted to Mr Neal.

COFFER DAM FOR PLACER MINING AND PIER BUILDING.—L. F Gilman, Spokane, Wash The object here is to provide details of construction for a coffer dam, which is adapted for erection at a selected point in a stream of water, and incloses an area of the bottom thereof, any suitable means for the removal of water from the dam being employed, to permit an excavation to be made in the soil thus exposed.

BARBER'S CHAIR.—A Fiore, Trenton, N J The seat in this chair is both revoluble and movable forwardly and rearwardly, and means are provided for positively locking the seat in successive positions against turning and means for locking the seat against forward and rearward movement, with a unitary device, such as a crank, for operating both of the locking means.

MEAT-HANGER.—J Fowler, New York, N Y. The improvement has in view a hanger in the nature of a clasp, which is adapted to be easily applied to and detached from a side of bacon or other similarly shaped piece of meat, and operative to firmly press on the meat at each side and give it the desired shape.

SIPHON.—W. P Christoforis and C De Lukacsevics, New York, N. Y This siphon is for use in dispensing beverages and some medicines. The bottle being filled with a liquid for instance carbonated water, the operator may discharge the contents of the bottle by merely pressing upon a knob. When the pressure is relaxed the bottle is closed automatically

POST FORMING MOLD.—W W Bailey, Chadwick, Ill This invention consists of a post forming device or mold which will permit of a post being formed in a somewhat wet condition, and one in which the act of removal of the side walls of the mold will cause a troweling action and produce a smooth finish to the sides of the finished post.

### Hardware and Tools.

DOOR-LOCK.—C R Wallin, New York, N Y In this patent the object of the invention is the provision of a new and improved door lock arranged to lock the main bolt against movement unless first unlocked by the key, to prevent withdrawal of the latter and duplication thereof by unauthorized persons.

BACK BAND HOOK AND CLAMP.—J P Freeman, Social Circle, Ga. Among the principal objects which the present invention has in view are: to provide a clamping device to take up or to splice a flexible member of harness for attachment of the same to a chain and to provide an implement of this character which is simple, economical and durable.

COMBINATION TOOL FOR MINERS' USE.—A V Des Moineaux Denver Colo The purpose in this instance is to combine and arrange in a novel manner a plurality of implements that are necessary for preparing explosive blasts, wherein dynamite in stick form is the explosive agent that is to be fired by electricity or other means.

RAZOR STROP.—R E Brown, Tidioute, Pa A means is employed to connect the strop with the swiveled suspending eye or device avoiding the usual bolt and nut arrangement generally objectionable for the reason that it wastes substantial length of the strop is bad in appearance scrapes and scratches wherever it contacts and is unsatisfactory in packing several strops together in a box

### Heating and Lighting.

GAS-BURNER.—H C Fares Monongah W Va Among the principal objects which the present invention has in view are: the provision of an apparatus wherein air, steam and gas are mixed and burned and the provision of an apparatus wherein the quantity of gas being mixed with the other ingredients may be regulated

### Household Utilities.

WINDOW CLEANER.—M Ax, Red Bank, N J One object of this inventor is to provide an improved means for detachably securing a wiper-strip upon a window cleaner A further object is to provide an improved form of tank and fabric-supporting means, whereby a fabric may be removably attached to the tank

REMOVABLE BROOM-PROTECTOR.—Bertha Clark New York, N Y In this case the object of the invention is to provide a device which can be attached to the head of a broom and which will operate as a protector for the broom straws so as to reinforce them. In this way the device has a tendency to increase the utility and durability of the broom to which it is attached

RECEPTACLE LIFTER.—J E. Wenman New Philadelphia Ohio. This lifter can be removably associated with cooking utensils or other receptacles of different kinds and sizes to permit their manipulation, which can be locked or clamped in position at the rim of a receptacle, by a simple manipulation which requires the use of but one hand, and which does not interfere with the use of a lid or cover upon the receptacle and can, in fact, be used to hold the cover in place

CLOSET FITTING.—W M Weatherly Greensboro, N C In the present patent the invention has for its object amongst others to provide a construction which will permit the closet to be used, when necessary, when roughed for standard fixtures and will also take standard closets with gasket arrangements.

PERCOLATOR.—B N Young Ottumwa Iowa The object is to provide in this invention a device which may be cheaply constructed, and which may be applied to existing coffee pots without any change therein The percolator is adapted for making postum and similar beverages There is no possibility of burning the beverages, since they are elevated above the bottom of the vessel

### Machines and Mechanical Devices.

TENSION DEVICE FOR WIRE SAWS.—J M Owens Oolitic Ind This device for wire saws of stone-sawing machines is arranged to permit convenient vertical and horizontal adjustment of the sheave, over which passes the endless wire saw to give the latter the necessary tension and to bring the saw into proper position according to the thickness of the slab to be cut from the stone block. The invention relates to stone-sawing machines such as shown and described in the Letters Patent of the U S., formerly granted to Mr Owens.

ROTARY PRESS.—J A Dowd, Fall River, Mass. There is provision in this invention for a device which will compress material efficiently and rapidly, and draw off the liquid expelled from the material, in a convenient and thorough manner It relates to a rotary press that forces the material to pass through a constricted neck, squeezing out the last particles of moisture

SPRING POST FOR WOODWORKING MACHINERY.—C T Conners, Long Branch, N J The object of this inventor is attained by providing a manually-controlled gearing for turning the post and locking it in the desired turned position by making the post vertically adjustable and providing means for locking it to the gearing and by providing a locking device for adjustably locking the spring finger to the post.

### Prime Movers and Their Accessories.

VAPORIZER HEATING DEVICE.—A P Osborn, New York, N Y This invention provides a means by which the headlight or other lantern of the automobile may be utilized to heat the vaporizer, so that when starting the machine it is only necessary to light the lamp which will furnish the heat necessary for starting the operation of the vaporizer and if desired this heat may be continued throughout the entire operation of the machine

STARTING EXPLOSION ENGINES.—J E. Malivert, 32 Rue Pergolèse Paris France The method in this invention effects the starting of the engine by admission to the cylinder of a charge of compressed air upon the stroke in which the explosion would be normally taking place and is characterized by the arrangement of a diaphragm valve for each cylinder for admitting compressed air from a receiver the operation of these valves at the correct moment for each cylinder being determined by a distributer in constant relation with the engine shaft normally maintaining upon the diaphragms a pressure of compressed air which balances the diaphragm and keeps the valve closed and releasing this balance pressure when the compressed air is to be admitted to the cylinder

GAS AND STEAM POWER-GENERATOR.—E. F Lamson Salt Lake City Utah The purpose here is to transpose the heat units of gas fuel into a mixture of steam and combustion gases suited in pressure and mass and temperature to supersede steam in operating those types of engine and by thus linking them to gas producing apparatus to embody a gas and steam power system which will retain the advantages of the steam engines and combine with them the thermal efficiency of the explosive gas engine

### Railways and Their Accessories.

SAFETY ATTACHMENT FOR RAIL BRAKES.—J H Wright Greensboro N C This invention pertains to apparatus for automatically operating the brakes of a railway train in case of accident to the trucks or from any other cause which tends to throw the trucks into an abnormal position The abnormal movement of the trucks in any direction will operate to set the brakes in an air brake system instantly and thereby stop the train

METALLIC RAILROAD TIE.—A M Baird Topeka Kan The invention relates to ties such as shown and described in three Letters Patent of the U S formerly granted to Mr Baird The tie plate spans a channel plate thus giving the desired flexibility to the tie thereby permitting the latter to successfully withstand the heavy pounding incident to powerful high speed locomotives passing over rails held on the metallic tie

TIE JACK.—I Bracken Litchfield Minn This jack is especially designed for use in lifting railroad ties and supporting the same beneath a rail during the spiking of the rail to the tie The jack will enable one man instead of three as formerly to replace ties in their proper position on the railroad track spike and tamp them

### Pertaining to Recreation.

GAME APPARATUS.—C I Renner, Pittsburg, Pa This game comprises a vessel for containing liquid a gate arranged transversely of the vessel and provided with an opening and a plurality of buoyant figures in the vessel and adapted to pass through the opening It is entertaining not altogether a game of chance and may be played by any number of players

### Pertaining to Vehicles.

SEAT SECURING DEVICE FOR WAGONS.—C W Barnes Mount Union Iowa This improvement provides novel details of construction for a seat securing device that may be readily connected with the body and seat of a wagon of the class of light freight wagons each provided with an oblong box like body having parallel sides and afford convenient and reliable means for detachably securing the seat transversely on the wagon body

CAR WHEEL AND AXLE.—H L Worthen Tucson Ariz. Ter This invention relates to car wheels and axles for general use and more particularly for service upon small cars used in mines and adapted to turn sharp curves The wheels are provided with hubs and are loose upon the ends of the axle Each hub has a ring like enlarged portion which works in a recess in the framework the wheel being by this arrangement prevented from leaving the shaft The two wheels upon the same shaft thus turn independently Provision is also made for lubricating both the axle and the wheels.

SYSTEM OF BRACING FOR TRACTION ENGINES.—W H Knorr, Tolstoy S D This invention relates to systems of bracing for traction engines, and is particularly useful in connection with such vehicle or other structures having spaced frame members supporting mechanism tending to distort the frame members, or adapted to be unequally loaded whereby the frame members are liable to distortion

Note.—Copies of any of these patents will be furnished by Munn & Co for ten cents each Please state the name of the patentee title of the invention, and date of this paper

## Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions books, etc This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 18th or will be sent by mail on request.

(12184) N C says I maintain that a person at North Cape Norway, on June 21st facing due north at midnight solar time will see the sun facing him. Supposing it possible for him to remain in such position twenty four hours, at 6 A M sun will be at his right at 12 M (noon) at his back, his shadow pointing due north at 6 P M at his left and at midnight again June 22d facing him as before The sun all the time is low in the heavens and in such position makes a complete circuit of the celestial sphere In a conversation with a friend who has been there that is to North Cape he says that facing the sun at midnight on or about date mentioned it would describe a comparatively small circle in the twenty four hours and would always shine in the face of the observer provided he maintained his position facing the north Will you kindly state which contention is the right one? A We will state the case of the midnight sun on June 21st as seen from the North Cape Norway On June 21st the sun is vertically over the Tropic of Cancer Its declination changes but 22 seconds in that twenty four hours hence we may say that he is all day long threading the Tropic of Cancer He is therefore 23 deg 30 min north of the Equator and 66 deg 30 min from the North Pole all that day of twenty four hours. The latitude of the North Cape is 71 deg. 10 min 40 sec N Leaving the seconds out of the account as also the effect of refraction for the present, we may say that the North Pole is 71 deg 10 min above the north point of the horizon of the North Cape, and the sun is 66 deg 30 min from the North Pole toward the north point of the horizon at midnight The difference is 4 deg 40 min which is about nine diameters of the sun At midnight on June 21st from the North Cape if you look to the north if it is clear you will see the sun about ten of its diameters above the horizon since refraction will raise it apparently about a diameter After midnight the sun swings on up toward the east and keeps on a circle 66 deg 30 min from the North Pole as it goes At noon then it will be to the south of the North Pole by the same distance and it will be above the north point of the horizon by a distance equal to the sum of 71 deg 10 min and 66 deg 30 min or 137 deg 40 min This is 47 deg 10 min south of the zenith, or about half way from the zenith to the south point of the horizon The writer of this has been to the North Cape and is describing what he has seen The sun on June 21st does not describe a small circle about a point near the horizon as seen from the North Cape It moves around the North Pole as it does on all other days of every year changing in its declination somewhat each day so that in the winter half of the year of the northern hemisphere the sun is south of the equator and in the summer half of the year it is north of the equator but all the time the axis of the earth controls its apparent daily motion as seen from the earth You are correct as to the motion of the sun over the sky to the east south and west during the day but wrong in thinking that it will be low toward the horizon all day long as we have shown above Your friend is wrong in saying that the sun will describe a small circle The circle is 66 deg 30 min radius It is the smallest one which the sun describes but all stars nearer the pole than 66 deg 30 min describe smaller circles than that since all stars describe circles around the poles The pole star describes a circle of 1 deg 10 min 45 sec radius.

(12185) C F H says As I understand it, the earth's hour circles are 15 deg apart and a degree is equal to 60 geographical miles. Now if the distance between each circle is 15 degrees and as the hour circles converge toward the poles, the mileage or the number of degrees for each hour must vary Which is it, and how is the mileage of each parallel figured? A Your difficulty about the degrees and the miles of longitude arises from not remembering that a geographical mile is one-sixtieth of a degree of the earth's equator

and not a sixtieth of a degree of longitude taken in any latitude one may please. A degree of longitude varies in length from the equator, where it is 60 miles long, to the pole, where it has no length. An hour is 15 degrees of longitude in every part of the earth, but not 900 miles. It is 15 times the number of miles the degree of longitude has in that latitude. The number of miles in a degree varies and not the number of degrees in a circle. There are always 360 deg. in any circle and always 24 hours in any circle of longitude, hence there are always 15 deg. in an hour even close to the pole itself.

(12186) P. H. T. says: May I trespass upon your kindness to the extent of asking for a little scientific information regarding the horse power of ocean surf waves? What I would like to know is: If the surf waves are 4 feet high, traveling 15 feet per second, and arriving seven to the minute, and it were possible to intercept an area 40 feet wide by 10 feet deep, say 400 square feet, and entirely absorb the energy, what do you figure would be the total horse power delivered by the seven waves, the interception being just outside the breaking line? Haswell gives some data under the head of "Waves of the Sea," but does not, I think, give any formula for ascertaining the horse power. A. It is not quite clear from your question whether the 400 square feet area is intended to be in the vertical or the horizontal plane. In the former case no power would be generated, as the movement of the water in waves before they break is only in the vertical direction, a wave consisting only of upward and downward motion of a successive series of vertical sections of the water. In the latter case it cannot be calculated what proportion of the area rests at one time upon one wave. In the transactions of the American Society of Mechanical Engineers, vol. xiii, p. 428, Albert W. Stahl, U. S. N., gives the formula for the energy $E$ of the whole wave length of a wave $H$ feet high, $L$ feet long and 1 foot in breadth, the length being the distance between successive crests, and the height the vertical distance between crest and trough:

$$E = 8 L H^2 \left(1 - 4.935 \frac{H^2}{L^2}\right) \text{ foot pounds}$$

If $N$ is the number of such waves per minute, the horse power of a series of such waves per foot of breadth is

$$\frac{E \times N}{33{,}000} = 0.0024 H^2 L \left(1 - 4.935 \frac{H^2}{L^2}\right)$$

(12187) M. P. V. says: If I am not asking too much, I would be pleased if you can help me out of trouble. I have a hot water heating plant in the house which has twenty radiators. Seventeen radiators work O. K., but the other three will not. I have written to the makers, but they could not tell me the cause of the trouble. The three that cause trouble are at the end of the pipe and branch from a cross; the cross is 1 inch, radiators pipe ¾ inch, the main is 1½ inch and reduced at the cross. Two pipes from the cross go to radiators on the first floor and the third pipe goes to the second floor. These three radiators return to a cross on the end of the return main. The pipes to the radiators on the first floor have a slight rise and the one to the second floor is vertical. There are no air traps, and I have had the pipes changed three times but with the same result. The expansion tank is placed on the radiator pipe before the end where the cross is placed. 1. Does it make any difference where the expansion tank is connected to system? A. The position of the expansion tank should not theoretically make any difference in the operation of the system, but we think in your case that it would be better to place it beyond, i. e., farther away from the boiler than the crosses to which the last three radiators are connected. 2. Should the end of the two mains be connected with a pipe other than through the radiator? All the radiators work from where the expansion is connected back to the furnace work O. K., but the three beyond this point will not work. A. There is no advantage to be gained by connecting the outflow of the return pipe otherwise than through the radiators. Such an arrangement, while probably increasing the average heat of the water in the pipes, would reduce the circulation of hot water through the radiators. The trouble is probably due merely to the three radiators in question being the most remote from the boiler; possibly also the expansion tank acts as a kind of hot water storage reservoir and radiates a good deal of heat itself, so that the radiators farther on receive colder water than those between it and the boiler. We would suggest putting the tank on the return from the farthest radiator to the cross or on the return pipe from the cross to the boiler.

(12188) C. A. J. says: Take a standard ¾-inch pipe nipple. Lock it in a pipe vise 4 inches from one end. Screw on an extra heavy socket coupling 1½ inch outside diameter with a 12-inch wrench as far as the socket will go. Question: If a man weighing 170 pounds bears his whole weight on the handle of the wrench, what is the twisting strain exerted on the ¾-inch nipple? A. If a weight $P$ acts at a distance $a$ from the center of a shaft (or pipe) so as to twist it, the moment of the applied force is $Pa$. For your case the introduction of the thick coupling makes no theoretical difference, although in practice you get a better grip on account of the limitations of the tool. The force tending to twist the pipe acting on the fibers most remote from the axis of the pipe is to the force applied at the end of the wrench inversely as the distance of those fibers from the axis is to the length of the tool, according to the law of levers. For example, if the weight of 170 pounds is applied 12 inches from the center of the pipe and the remotest fibers are 5/16 inch from the center, $P = 170 \times 12 \div 5/16$, $P = 6{,}528$ pounds.

The twisting strain required to break the pipe calculated by the formula

$$Pa = 0.1963 \frac{d^4 - d_1^4}{d} S_s$$

in which $P$ equals the weight acting at a distance $a$ from the centre of the shaft or pipe, $d$ equals the external and $d_1$ equals the internal diameter of the pipe, and $S_s$ equals the unit shearing resistance of the material of the pipe. The latter may be taken as the same as the direct shearing resistance, say 45,000 pounds for wrought iron.

(12189) C. B. F. says: 1. Selective radiation, as I understand it, seems in defiance of the law that all bodies emit the same intensity of light at the same temperature. Kindly explain selective radiation. A. The fact is incontrovertible that bodies exert absorption of light and heat selectively, and hence also radiate selectively. This being established, it cannot be "in defiance" of any other law or fact. Laws do not thus defy each other in nature. Kirchhoff showed that the emissive and absorbing powers of all bodies at the same temperature for a given color are proportional when the radiation is a pure temperature effect. (Duff, "Physics," page 451, price $2.75.) But there are many substances whose luminosity is not a pure temperature effect. Considerable space is given to this topic in Barker's "Physics," which we send for $1.75 postpaid. 2. Where can I secure information concerning the telectroscope (electrical vision apparatus) of the Anderson brothers of Denmark, notice of which recently appeared in the SCIENTIFIC AMERICAN? A. We have no other information concerning the telectroscope than is given in the reference which you make. 3. Where can I secure a complete account of Tesla's experiments with high tension currents? A. No complete account of Tesla's work with high potentials has been published. We can supply you with a small book with the title "Experiments at High Potentials," for $1, giving the principal part of the work.

(12190) J. R. asks: How does science explain the gyroscope phenomena? A. The gyroscope illustrates the persistency with which a rotating wheel resists any effort to twist its axis out of its position, or rather to turn the plane of the wheel out of its position. When the wheel is made very heavy and spun around very swiftly, it becomes very hard to turn it sidewise at all. Such a wheel is able to hold a car on a single rail from upsetting. This is the principle of the monorail car which has attracted so much attention recently. We published an illustrated description of this in three issues of the SCIENTIFIC AMERICAN, price 10 cents each mailed. We have published a number of articles regarding the theory of the motion of the gyroscope. You will find them in the SCIENTIFIC AMERICAN SUPPLEMENT Nos. 1644, 1645, 1649, price ten cents each. We can also supply the following books: "Elementary Treatise on the Theory of Spinning Tops and Gyroscopic Motion," by Crabtree, price $1.50; also "Rotary Motion as Applied to the Gyroscope," by Barnard, price 50 cents.

(12191) J. M. asks: Can you tell me at what rate light travels? A. Light travels with a velocity of 186,000 miles a second. This has been measured with a good degree of accuracy by both Michelson and Newcomb separately at Washington. For their determinations see our SUPPLEMENT Nos. 193 and 557, price ten cents each.

(12192) S. N. S. says: If you have the information in memory or conveniently accessible, please tell me the cost or approximate cost per mile of any part of our subway railways and any part of any two-track city trolley line, though I would rather have the approximate average cost of subways and trolleys (cost of line only, everything except rolling stock and power stations). A. It is very difficult to obtain exact figures for the cost of excavation of New York or other subway railways, and division of the total cost by the total length may make the cost per foot or mile very wide of the mark for any individual foot or even mile on account of the great variation of ground and method. A general article on the New York subaqueous and subterranean railways in the April 1907 number of the Engineering Magazine gives a good idea of the reasons for this discrepancy, or you could obtain a list of articles covering the subject from the Engineering News. With the great variety of subjects we have to cover we cannot keep statistics of any one subject so closely. The cost of the Pennsylvania Railroad improvements from Newark to Long Island City, including hard rock tunneling under Manhattan with low first cost of equipment but expensive in time and labor, and shield tunneling in silt under the rivers, rapid and cheap in execution but expensive in first cost of plant, would work out at about $2,000 a foot for a two-track subway. The included cost of the huge and costly terminal station is balanced by the comparatively low cost of several miles of embankment railroad only from Newark to Bergen Hill. The Brooklyn extension of the present subway, with smaller tunnel and no expensive stations but much the same variety of excavated ground, cost only about $300 a foot. Construction of ordinary city street railways would rarely approach a tenth of that figure. You will understand from the foregoing that these figures are the merest approximations.

(12193) R. W. says: I wish to get a solution of a problem which has puzzled me for some time. I understand that a horse-power is a definite thing. I have a small automobile whose engine is rated at 20 horse-power. The cylinders are 3⅝ inches diameter by 4 inches stroke. I also have a four-cylinder marine engine whose cylinder diameter is 4⅝ inches diameter and 5½ inches. Now both of these engines are rated at 20 horse-power. Would you be kind enough to show me why there is such a difference in size? A. You are correct that a horse-power represents a perfectly definite amount of work done in a given time, 550 foot-pounds per second or 33,000 per minute. Gasoline engine rating is however rather more arbitrary than that of steam engines and not always so closely related to test figures. In either case the number of foot-pounds of work done is the product of the piston speed by the mean effective pressure, and if your two engines have been accurately rated by their makers, and each gives approximately 20 brake horse-power, the only explanation is that the one with the larger diameter and stroke of cylinders must compress and also explode the gas to a lower pressure, or have a longer proportionate expansion, making the mean effective pressure less.

(12194) H. M. S. says: On November 20th I observed a star about two points north of east and about ten degrees above the horizon. This star as I watched it became alternately a bright red and a pale yellow. Can you explain this? A. The star which you observed is Aldebaran of the Constellation Taurus. The changes which you observed in its light and color are entirely atmospheric effects due to the slightly different paths which the rays take through the atmosphere. These changes are greater at some times than at others. They are wholly in the air, and not in the light of the star at all. 2. At the same time I also saw a very large and brilliant white star (or planet) about two points west of S. W. by W., and between twenty-five and thirty degrees above the horizon. Can you tell me what star it was? A. The bright object is the planet Venus, which is moving away from the sun to the east and so is our evening star in the western sky. Your estimate of its altitude is too large. Degrees near the horizon are deceptive, just as the apparent sizes of the sun and moon at rising are deceptive.

(12195) E. R. says: In 1900 Dewar obtained a temperature of −260 deg. C. by evaporating liquid hydrogen. Has a lower temperature been obtained since, and how? Is it possible to obtain a temperature below −273 deg. C.? A. Much has been done since 1900 in the production of low temperatures. In 1908 the last remaining gas was liquefied by Kamerlingh Onnes of Leyden, Holland. Helium, under a pressure of 100 atmospheres, was cooled in a bath of boiling hydrogen to −258 deg. C., the boiling point of hydrogen. Then it was still further cooled by the regenerative process, and liquefied. The boiling point of helium under atmospheric pressure is about −268.5 deg. C. By boiling it under a pressure of one centimeter of mercury the temperature is lowered to −270 deg., or 3 deg. above absolute zero. There is no substance known by which the cooling can be carried further, and there is little hope of reaching −273 deg., or absolute zero, by any means within our power.

(12196) P. T. says: Will you be kind enough to answer for me the following: If, for instance, a bricklayer's plumb bob was suspended in a vacuum and kept perpendicular, moving through space on the surface of the earth at a uniform speed of say 60 miles per hour, would the plumb bob show a true perpendicular or would it be slightly out, and if so would this be noticeable to the naked eye? A. A plummet would not deviate from a perpendicular by being in a vacuum. Gravity acts in a vacuum just as it does in the air. Nor would it be affected by a velocity of 50 miles per hour in a vacuum. It is going very much faster than that at present by the motion of the earth through space, at the enormous velocity of 18 miles a second. It is also moving with a velocity of 1,000 miles per hour on the equator by the eastward rotation of the earth upon its axis, and more than three-quarters as fast as that in the latitude of New York. Balls fall somewhat to the east of the point from which they are dropped, but this is due to another cause, the fact that they go from a level of more rapid to one of less rapid rotation of the earth. See Young's "General Astronomy," which we send for $3 postpaid.

(12197) C. J. H. says: A bets that the motorcycle has been driven to a higher speed than the automobile, and that the records show it. B bets that the automobile has been driven the faster. Who is right and what is the record? A. In reply to your query, the automobile has made faster time than the motorcycle. Marriott's mile on the Stanley steamer at Ormond Beach in 28 1/5 seconds (127.65 miles an hour) is, we believe, the record. G. H. Curtiss claimed he made a mile in 26 2/5 seconds on an 8-cylinder, 90 H. P. motorcycle of his own make at Ormond, but this was not official. The motorcycle record for a mile, 42 3/5 seconds, was made on a track by Fred Huyck.

(12198) A. W. S. says: We have trouble with resonance or echo in our church, which is very annoying. The audience room is about 70 feet long, by 40 feet wide. The speaker's desk is in the center of one side, in front of organ and choir. We are considering the matter of stretching a wire the length of the church at some distance from the speaker and in front of him. Will you kindly tell us if a wire would at all relieve the situation? Would several wires be more likely to relieve the trouble? How far relatively from speaker toward opposite wall should a wire or wires be placed, and how high? A. The echo in your church will not be remedied by one wire, nor perhaps by a large number of wires run across the room. The belief formerly was that a set of fine wires so fine as to be nearly invisible, could be stretched across the room above the heads of the audience, perhaps ten feet from the floor, and that these would break up the sound waves. Hundreds of wires were thus used, ranging back through the room, at the same height, covering all the space. The best remedy for an echo is a full audience. Next, the hanging of loose curtains of soft materials on the walls. Prof. W. C. Sabine of Harvard University, Cambridge, Mass., has made many experiments in this matter. You will find an article upon his work in our SUPPLEMENT No. 1772, which we will send for ten cents.

(12199) W. J. W. says: How cold would it be if it were twice as cold as zero? A great many answers have stated that it would be 230 deg. Fahrenheit below the Fahrenheit zero, working from the basis that absolute zero Fahrenheit is 460 deg. below the Fahrenheit zero. A. Absolute zero is the temperature at which all heat would be removed from a body, or the temperature at which molecular motion would cease. From the observed fact that all gases contract 1/273 of their volume by cooling from zero Centigrade to one degree below zero, it is inferred that absolute zero is −273 deg. Centigrade, or −459.4 deg. Fahr. This is to be found in all the larger textbooks of physics. The degrees from absolute zero express the relative quantity of heat. Degrees of a thermometer do not give any idea of the relative quantity of heat, but only of relative temperature. The correct answer, if there be one, to the question "How cold would it be if it were twice as cold as zero Fahrenheit?" is that it would be 229.7 deg. below zero. For the theory of gases on which the absolute zero is based see Carhart's "University Physics," vol. II, page 29, etc.

(12200) H. B. says: Can you tell me whether a photograph has ever been sent by wireless telegraphy or whether it would be possible? A. We have never heard of sending a photograph by wireless telegraphy, and we are sure we do not know whether it is possible or not. He would be a rash man who would set the bound for the possible in this world of science.

(12201) A. G. asks: I have been trying to build a Wimshurst electrical machine as described in the SCIENTIFIC AMERICAN SUPPLEMENT No. 48, but I have never been able to procure the brass balls to tip the rods and tubes with, that is, solid brass ball. I can get plenty of hollow brass balls. Would there be any kind of composition or filling a person could fill in the hollow brass that would answer the purpose, just as well as the solid brass? A. It is not necessary that the brass balls of a Wimshurst machine should be solid. They will work just as well if hollow, but they are not as strong as if solid. You may fill them with anything to make them stiff and strong. Even a wooden ball covered with tin foil would serve the purpose, but to a less degree, since its surface would not be smooth. Only the surface of the metal on a static machine takes part in the electrical action of the machine.

(12202) W. M. asks: Can you supply me with a formula to meet the following case: It is desired to calculate the quantity of water delivered and height of jet from the nozzle of a fire hose when the following details are given, viz., head of pressure at fire engine or elevated tank, length and diameter of pipe, total fall, size of delivery nozzle. I have all the usual hydraulic formulas and tables giving flow of water in pipes and loss of head due to friction in pipe. From this latter cause (friction) it will be found that a moderately long pipe, say 1,000 feet, of moderate diameter, say 3 inches, having a head of 100 feet, will have all the head absorbed in friction, but in practice I actually get a moderately good fire stream through a 7/8-inch nozzle. It is understood that this result is obtained by the small orifice of nozzle delivering less quantity, and causing a reduced velocity of pipe, and therefore less loss of head, but I find no formula or rule whereby to work out the problem before described, viz., quantity delivered and height of jet. Books do not handle this special question. A. In further reply to your letter, the height of a jet of water thrown from a

fire-hose nozzle is calculated by the formula $h = KH$, in which $h$ = the height of the jet in feet, $H$ = the head of water in feet (or head corresponding to the pressure, 0.43 pounds to the square inch pressure = 1 foot head), and $K$ = a coefficient varying with the ratio of the diameter of the jet to the head as follows

| | | | | |
|---|---|---|---|---|
| If $H = d \times 500$ | 600 | 1000 | 1500 | |
| $K =$ | 0.96 | 0.9 | 0.85 | 0.7 |
| If $H = d \times 1800$ | 2800 | 3700 | | |
| $K =$ | 0.6 | 0.5 | 0.25 | |

For the case you mention your 100 feet of head = $H$, and $d$ = 7/8 inch, so $H = 1370 \times d$ and the coefficient $k$ = 0.74. The theoretical height of the jet should therefore be 0.74 × 100 = 74 feet. The head $H$ must be corrected, however, by the friction in pipe and hose. The loss of pressure or its equivalent loss of head may be calculated by the formula $h = v^2 (4m) \frac{l}{2gd}$, in which the constants are $d$ = 3 inches diameter of pipe (in your case) = 0.25 foot, $l$ = length of pipe = 100 feet and $2g$ = 62.4, and the variables are $v$ = velocity of water in feet per second, $h$ = loss of head per 100 feet of pipe, and $m$ = a coefficient found by experiment. The velocity $v$ must be calculated from the measured discharge of a given pipe, i. e., the cubic feet of water discharged per second by the sectional area of the hose. The coefficient $m$ varies from 0.0045 for a discharge of 200 gallons per minute or a velocity of 13.07 feet per second in a 2½ inch pipe to 0.00482 for 500 gallons per minute or 32.67 feet per second in a 2½ inch hose. A simpler but less closely approximate formula for loss of head is $h = \frac{lq^2}{1801 d^5}$, in which $h$ is loss of head in feet as before, $l$ = length of pipe in feet, $q$ = quantity of water discharged in gallons per minute, and $d$ = diameter of hose in inches. We regret that we cannot conclude the calculation for you as you do not mention the quantity discharged which prevents our arriving at the values of $v$ and $m$ in the second formula or $q$ in the third but from your discussion of the subject we have no doubt that with the above particulars you will easily be able to calculate the height of the jet yourself

## NEW BOOKS, ETC.

**Elements of Machine Design.** By Dexter S. Kimball, A.B., and John H Barr, M.S., M.M.E. New York: John Wiley & Sons, 1909. 8vo., pp 446, 196 cuts. Price, $3.

This work is the outgrowth of the experience of the authors in teaching machine design at Cornell University. The first three chapters are introductory, taking up the fundamental principles of machine design, a brief discussion of energy and force problems, and the more important straining actions, with formulas for strength and stiffness. Chapter IV takes up lubrication and efficiency, while the remainder of the book deals with important machine details illustrating the application in practice of the theoretical considerations discussed in the first part of the book.

**Direct and Alternating Current Testing.** By Frederick Bedell, Ph.D., assisted by Clarence D. Pierce, Ph.D. New York: D. Van Nostrand Company, 1909. 8vo., pp 265. Price, $2.

This work has been prepared primarily for students, although it will doubtless be found helpful to others. It consists of a series of tests on direct and alternating current apparatus, which are explained in such a manner that the reader's attention is directed to the principles underlying the experiments and the significance of the results. Such tests as require special apparatus or unusual testing facilities are left out of the text proper, though they are described in the appendices to the various experiments.

**Lessons in Telegraphy.** By Charles Henry Sewall. New York: D. Van Nostrand Company, 1909. 12mo., pp. 88. Price, $1.

The book is intended as a textbook for schools and colleges and is intended to furnish the student not only with the ordinary instructions necessary to learn the art of telegraphy, but also takes up the negative side of the study, telling the student what not to do, and thereby preventing him from forming bad habits which might be difficult to remedy later on.

**Radiation, Light, and Illumination.** Series of engineering lectures delivered by Charles Proteus Steinmetz, A.M., Ph.D., compiled and edited by Joseph Le Roy Hayden. New York: McGraw-Hill Book Company, 1909. 8vo.; pp. 305; 127 cuts. Price, $3.

These lectures by Professor Steinmetz before the students in electrical engineering at Union University have been compiled not only to provide a textbook of illuminating engineering, but also to provide the public at large with a knowledge of light and radiation. For this reason mathematics have been avoided in all the lectures except two, which by their nature are mathematical and are intended for the illuminating engineer. However, the general reader who has little knowledge of mathematics may avoid these two chapters without serious

**College Algebra.** By H. L. Rietz, Ph.D., and A. R. Crathorne, Ph.D. New York: Henry Holt & Company, 1909. 12mo., pp 261. Price, $1.40.

Recognizing the fact that a considerable period of time elapses in most cases between the completion of the high school algebra and the beginning of college mathematics the authors have devoted the first part of the text book to a review of high school algebra. At the same time new matter is introduced which his added maturity enables him to appreciate. In treating the more advanced portion of the subject many topics usually found in textbooks and college textbooks are omitted and the matter is restricted to the development of those central points which the experience of the authors has shown to be essential.

**Alternating Current Motors.** By A. S. McAllister, Ph.D. Third edition. New York: McGraw-Hill Book Company, 1909. Pp 322, 138 figures. Price, $3.

The present edition has been enlarged and revised, and takes up the recently developed "split pole" variable-ratio synchronous converter and contains a chapter on synchronous motors, in which the characteristics of this machine as a motor and as a "condenser" are fully treated. The chapter on prevention of sparking in single-phase commutator motors includes the latest improvements in commutating pole motors.

**Theoretical Elements of Electrical Engineering.** By Charles Proteus Steinmetz, A.M., Ph.D. Third edition. New York: McGraw-Hill Book Company, 1909. Pp 455, 239 illustrations. Price, $4.

The present work is in a certain respect supplementary to "Alternating Current Phenomena" and contains specific discussion of the different features of individual apparatus, presenting the most important electrical apparatus and their action under normal and abnormal conditions. The first edition, which was published eight years ago, is now revised and much enlarged, so as to bring it up to date in theory and practice. The author recommends that this book be read in parallel with the first seventeen chapters of "Theory and Calculation of Alternating Current Phenomena," as in this way a close insight into the nature and behavior of the apparatus will be obtained.

**Dynamo Laboratory Manual for Colleges and Technical Schools.** Vol. I. Direct-Current Studies and Tests. By William Suddards Franklin, with the co-operation of Stanley S. Seyfert, and Clarence E. Clewell. New York: The Macmillan Company, 1909. 12mo., pp 152. Price, $1.75.

The authors describe a series of laboratory experiments for students, many of which are chosen primarily for their educational value, while others are such as are sometimes carried out in practice. The directions are very complete and practical, and the authors suggest that the students be thrown upon their own resources in performing the experimental work so that they will become accustomed to translating scientific writing into ideas of reality and also develop manual dexterity.

**Astronomy From a Dipper.** By Elliot C. Clarke. Boston and New York: Houghton, Mifflin Company, 1909. Pp 66. Price 60 cents.

The object of this book is to acquaint the amateur with the positions of the constellations and the names of the principal stars. The Great Dipper is used as the spot from which the various constellations are pointed out, hence the odd title of the book. The subject is considered in a semi humorous vein and the object is well carried out by the author, who claims that because he knows but little more than his readers he is for this reason eminently fitted to be their teacher.

**Electric Railway Troubles and How to Find Them.** By Paul E. Lowe, M.E. Chicago: Frederick J. Drake & Co., 1909. 12mo., pp 267, 118 figures. Price, $1.50.

This is a book for motormen and is designed to acquaint them with the mechanism of their cars and enable them to make their own repairs in emergencies. Their author aims to avoid complication and endeavors to explain everything in the simplest terms possible and in a thoroughly practical manner. In order that the motorman may fix the matter in his memory, a "Repair Catechism" is included in the book, which contains 109 questions and answers.

**Compressed Air.** By Lucius I. Wightman, E.E. Chicago: American School of Correspondence, 1909. Large 8vo., pp. 168.

This is a reference work on the production, transmission, and application of compressed air; the selection, operation, and maintenance of compressed air machinery and the design of air power plants. Compressed air and electricity to-day share between them the great field of power transmission, to the practical exclusion of all other transmission agents. Steam, because of its rapid condensation, can hardly be considered as a practical power transmitter for any but the shortest distances. Hydraulic transmission has had no general application. Mechanical means of transmission, such as shafts, belts, ropes, chains, and gears, are necessarily very limited in their possibilities. Compressed air and electricity, on the contrary offer almost unlimited possibilities of extension and of diversified application, and in all cases, where properly applied, they are entirely successful when measured by the modern standards of commercial economy. With the relative merits or shortcomings of compressed air and electricity as power transmitting agents the work has nothing to do. Modern engineering has defined with reasonable clearness, the respective fields of these agents, into either of which the other agent cannot hope to enter with any degree of success. The rivalry of the earlier days between these two forms of power transmission has given place to a mutual recognition of one another's merits and cordial co-operation in certain classes of work for which neither alone is fully adapted. The illustrations are numerous.

**Wood Products: Distillates, and Extracts.** By P. Dumesny and J. Noyer. Translated from the French by Donald Grant. London: Scott, Greenwood & Co., 1908. New York: D. Van Nostrand & Co. 8vo., pp 320. Price, $4.50.

The literature on wood products which are obtained by distillation and extraction is very limited, so that the present volume will be warmly welcome. The work is divided into two parts, the first dealing with the chemical products of wood distillation and the second with dyeing and tanning extracts obtained from wood. The chapters deal with the principal method of distilling wood, the acetic acid industry, the secondary products of wood distillation, the analysis of raw materials and finished products, the extraction of extracts, etc., for tanning and other purposes. The work is well illustrated by appropriate engravings.

**The Problem of Evil.** A Criticism of the Augustinian Point of View. By Marion Leroy Burton, B.D., Ph.D. Chicago: The Open Court Publishing Company, 1909. 12mo., 234 pp. Price, $1.25.

The readers of this book are warned at the outset that the work is not intended for the popular reader, but is a detailed technical criticism of the philosophical basis of the Augustinian treatment of the problem of evil. The last chapter however summarizes the conclusions of the author and may be taken up with interest by those who do not care to delve into the arguments by which the author has arrived at his position. A partial list of Augustine's own works and such other books as the author has found useful in preparing his criticism is given.

**The Apocryphal Acts of Paul, Peter, John, Andrew and Thomas.** By Bernard Pick. Chicago: The Open Court Publishing Company, 1909. 12mo., 376 pp. Price, $1.25.

The present work is the first attempt to make the researches of Lipsius and Bonnet on the Apocryphal Acts of the Apostles and Schmidt's Coptic Acta Pauli accessible to the English reader. Only the older and more important Acts are taken up in the present volume. Although these Acts contain both truth and fiction, they are of importance as giving us a picture of Christianity toward the end of the second century and form an important contribution to the primitive literature of the Church. The text is accompanied by copious notes, particularly that part dealing with the Acts of Paul.

**Star Gazer's Hand Book.** A Brief Guide for Amateur Students of Astronomy. By Henry W. Elson, Ph.D. New York: Sturgis & Walton Company, 1909. 16mo., 55 pp., 4 plates. Price, 50 cents.

The author, who has presented the subject of astronomy at teachers' institutes and similar gatherings, has compiled the present handbook at the special request of a number of teachers. In a very condensed form and without the use of mathematics, the main astronomical facts are given. The constellations are dealt with in particular with the mythological stories relating to them.

**Castles and Chateaux of Old Burgundy and Border Provinces.** By Francis Miltoun. Boston: L. C. Page & Co., 1909. 12mo., 333 pp. Price, $3.

The old Burgundian Province was closely allied topographically, climatically, and by ties of family with many of its neighboring political divisions, and it is for this reason that this section of France is of particular interest. Not in the royal domain of France itself, not in luxurious Touraine, were there more of splendor and the costly trappings of the ceremonial of the Middle Ages than in Burgundy, which has ever been a land of prosperity and plenty. To the traveler in France this section of the country affords particular advantages: access is easy, owing to good means of communication by a network of railroads. The author has presented the subject in a most interesting manner, and the illustrations by Blanche McManus are reproduced from paintings made upon the spot. The book is handsomely printed and bound, and is most luxurious.

**The Wonders of Asiatic Exploration.** By Archibald Williams, B.A., F.R.G.S. Philadelphia: J. B. Lippincott, 1910. 12mo.; pp. 159. Price 75 cents.

The titles of the chapters of this interesting book are as follows: Four Years in the Wilds of Asia, Further Adventures in Eastern Turkestan and Tibet, Surveying in Mid Asia, Lhasa Visited, From Manchuria to the Pamirs, An Adventurous Journey Among Celestials and Lamas, The Strange People of the East Indian Archipelago, The Unexplored Peaks of New Guinea. The contents of this book have been taken from Mr. Archibald Williams's larger book entitled "The Romance of Modern Exploration," and a chapter on Exploration in New Guinea by Mr. Norman Davidson has been added. The book is a very timely one giving the very latest information available.

**The Wonders of Animal Ingenuity.** By H. Coupin, D.Sc., and John Lea, M.A. Philadelphia: J. B. Lippincott Company, 1910. 12mo., pp 163. Price, 75 cents.

This attractive book deals with some of the wonderful activities of the animal world. The first chapter deals with "Master Craftsmen," the second and third chapters with "Excavators and Miners," then comes a chapter on "Makers of Baskets," then one on "Architects of Spherical Dwellings." Then there comes a chapter on "Makers of Mounds: Ants." This is followed by the "Mounds Made by Birds," then come two chapters on "Masons." An entirely new concept of the animal world is obtained by a perusal of this fascinating book which has an extremely ugly cover.

**Makers of Electricity.** By Brother Potamian, F.S.C., D.Sc. Lond., Professor of Physics in Manhattan College, N. Y., and James J. Walsh, M.D., Ph.D., LL.D., Dean and Professor of Nervous Diseases and of the History of Medicine at Fordham University School of Medicine, Professor of Physiological Psychology at the Cathedral College, New York. New York: Fordham University Press, 1909. pp 404.

Dr. James J. Walsh who with Brother Potamian presents this new series of biographies, attracted not a little attention in literary and scientific circles with his "Makers of Modern Medicine" and "The Popes and Science," in which books he discussed ardently and it must be confessed with justice the valuable scientific contributions made by that very Catholic clergy of the Middle Ages which is popularly supposed to have done all in its power to prevent the spread of learning. In the volume before us we have no systematic attempt to thwart the purposes of biography by fostering those of religion although it is distinctly pointed out in the preface that every one of the men whose lives are discussed, from Peregrinus and Columbus to Lord Kelvin, were all of them men of deep religious convictions. On the whole one will find in this book very good sketches of the lives of the great pioneers in electricity with a clear presentation of how it was that these men came to make their fundamental experiments and how we now reach conclusions in science that would have been impossible until their work of revealing was done. The biographies published are those of Peregrinus, Columbus, Norman and Gilbert, Franklin and some contemporaries, Galvani, Volta, Coulomb, Oersted, Ampère, Ohm, Faraday, Clerk Maxwell and Kelvin.

**Power, Heating and Ventilation.** A Treatise for Designing and Constructing Engineers, Architects and Students. By Charles L. Hubbard, B.S., M.E. Part I, Boiler Room Equipment, first edition. Brattleboro, Vt.: The Technical Press, 1908. 8vo., pp 216. Price, $3.

The matter contained in this volume had its beginning in a pocket note book which in turn served as a basis for articles which appeared in the Technical Press from time to time. Occasional calls for reprints of these articles led the author to select those having the most practical value and to combine with them others to form sufficiently new material to make up a treatise on power and heating plants. The subject of power is treated more especially from the steam side but there is also reference to the requirements of electric lighting and the distribution of electric power. No attempt has been made to cover central station work but plants similar to those found in factories, office buildings and institutions. The illustrations are excellent, the wax process being used exclusively.

**College Text Book of Geology.** By Thomas C. Chamberlin and Rollin D. Salisbury. New York: Henry Holt & Co., 1909. 12mo., pp 978. Price, $3.50 net.

For a number of years there has been room for a thoroughly modern work on geology which can be used as a text book. At last we have an ideal book a perusal of which will benefit anyone whether he is interested in the subject or not. He certainly will be after he has finished a few of the chapters. The book is elaborately illustrated with fine engravings and a considerable number of plates, many of them in color. The illustrations in nearly every case are made from original photographs and are a great relief from the time-honored illustrations which one is wont to see in his geology. In brief the book is divided into two parts: first, Dynamic and Structural Geology; second, Historical Geology. Under the first part the materials of the earth and their arrangement, The Geological Work of the Atmosphere, Land Waters,

Ground (Underground) Water The Work of Snow and Ice The Work of the Ocean Lakes, Movements and Deformations of the Earth's Body Vulcanism, and Structural Geology In the second part we have The Origin of the Earth The Archeozoic Era The Proterozoic Era The Paleozoic Era, which is in turn divided into the Cambrian Period The Lower Silurian The Upper Silurian The Devonian, the Mississippian the Pennsylvanian the Permian Period We then come to the Mesozoic Era which is divided into the Triassic Period the Jurassic Period the Cretaceous Period. Now comes the Cenozoic Era which is divided into the Eocene Period, the Miocene Period the Pliocene Period the pleistocene or Glacial Period and the Human or Present Period A perusal of this work will give the reader an excellent idea of the whole subject

A Handbook of Polar Discoveries By A W Greely, Major-General United States Army Fourth Edition, Revised and Enlarged Boston Little, Brown & Company, 1909 pp 336 Price, $1 50

Major-General Greely, himself an Arctic explorer of distinction has performed a notable service in gathering in an authoritative handbook records of the principal expeditions made from the time of the early northwest voyages down to the year of 1909 In view of the Cook-Peary controversy naturally one turns with some curiosity to those chapters of the book in which the claims of Cook and Peary would necessarily be discussed General Greely finds himself constrained to give full credit to both notwithstanding the sharp attacks which have been made upon the former Of his own courageous explorations he writes with characteristic modesty and yet as fully as the historical value of his work demands General Greely's volume represents more than 70,000 pages of narrative from which he has endeavored to compile such data of accomplished results as may subserve the inquiries of the busy man who often wishes to know what when and where rather than how

Mendel's Principles of Heredity By W Bateson, M.A., F.R.S., V M H Fellow of St. John's College, Professor of Biology in the University of Cambridge Cambridge, at the University Press New York G P Putnam's Sons, 1909 pp 396

Mr Bateson is well known to students of biology as an authority on breeding and heredity In the present volume he has given a succinct account of the discoveries which have been made by the practical application of Mendel's method of research As a result of Mendel's work and its application by modern biologists in which task Mr Bateson himself has played no small part the study of heredity has become an organized branch of physiological science, already abundant in results and in promise Although the subject is by no means exhaustive, still at the present time our knowledge of the facts has reached a definite stage, and a book in which the phenomena of heredity are scientifically presented is certainly needed Such a book Mr Bateson has presented and presented moreover very ably when it is considered how diverse and many are the facts zoological and botanical, from which the material must be drawn

# INDEX OF INVENTIONS

**For which Letters Patent of the United States were Issued for the Week Ending January 25, 1910,**

**AND EACH BEARING THAT DATE**

[See note at end of list about copies of these patents.]

A NEW STORAGE BATTERY STREET CAR.

(Continued from page 130.)

mobiles and electric trucks. So far they have failed to develop any serious difficulties. It took the utmost patience on the part of Mr Edison to develop the battery to a state which he now considers practically "fool-proof." Naturally the public has not been so patient and has been grumbling about the long delay in developing this battery concerning which so much has been promised.

The other day the public was invited to inspect a street railway car equipped with the new batteries, which was run on a short section of track in West Orange. This car differs materially from the ordinary car not only in the power source, but in general design The amount of current to be stored in the battery is limited, and in order to make this power go as far as possible it was essential that all superfluous weight be eliminated. The question of weight is not so vital a matter in the ordinary street car and has never received a great deal of attention. Mr Ralph A. Beach, who has been Mr Edison's assistant in adapting the storage battery to traction, was called upon to build a special car that would be as light as possible He found that the common street car is merely a smaller and slightly modified steam railroad car, and it was necessary for him to branch out on entirely new lines. He guarded as jealously against unnecessary weight as the builder of an aeroplane The backbone of the car he evolved consists of two 18-foot lattice girders which extend the entire length of the body under the seats They consist of electrically welded steel bars and are so inflexible that when loaded with two tons at the center they show a deflection of but 3/1000 of an inch Around these two girders the car is built In the first place they form a casing to receive the batteries of which there are 210 cells, 100 on each side for power and 10 for lighting All the superstructure of the car is built of veneer and light woodwork with the exception of the strap rails and posts, which are of bicycle tubing and act as a framework to support the weight of the roof The roof itself consists of a single sheet of veneer bent to the proper form, and is so light as to permit of making the side posts much smaller than in the ordinary car The fact that this car does not have to support a trolley pole has allowed of using so light a roof.

The truck contains many novel features. The connection between the truck and body is such as to permit of a side and end movement of but ¼ of an inch, although it may move vertically to a much greater degree The object of this is to insure smooth running and to prevent the usual swaying. In place of the usual car wheels light steel wheels are used The axles are divided at the center, being connected by long sleeves which permit one wheel to gain upon its mate when rounding curves or in case of a slight difference in their diameter In this arrangement will be seen the influence of the automobile There are other features as well which remind one of the automobile and show a radical departure from the common car construction In place of gearing the motors directly to the wheels a silent chain drive is used which, as automobile practice has shown, furnishes a more economical transmission owing to the fact that a large part of the sprocket wheels is in mesh with the chain, whereas in the spur gear transmission only one tooth, or at most, three teeth of the pinion, can engage the teeth of the gear. Furthermore the chain drive permits of a greater gear reduction. Commonly a 3 to 1 reduction is the most used on railway cars, whereas on the storage battery car a reduction of 6 to 1 is employed. This permits of using lighter motors, and hence forms one of the principal reasons why a chain gear was adopted.

The car is equipped with two 5-horse-power 110-volt motors which are of a very light construction. During the recent tests the car maintained a maximum

(Continued from page 132.)

speed of 15 miles per hour. The total weight of the car is estimated at 5 tons, and will seat 26 passengers, whereas the ordinary street car of the same size weighs twice that amount. The battery weighs 2,700 pounds, the car body 3,500, and the truck complete 3,800 pounds. It is claimed that the capacity of the batteries is sufficient to run the car continuously for 150 miles, although in regular street traffic, where a car is obliged to stop and start and crawl behind trucks, a single charge would probably carry the car but half this distance. The car is to be tested on West Street, in this city, where an excellent opportunity will be given it to demonstrate its efficiency for regular street service not only as regards the battery, but the light car construction as well.

## ARTIFICIAL PRODUCTION OF THE VOICE.

(Concluded from page 120.)

emitted by the larynx were recorded by a phonograph. The following conclusions were reached:

When the larynx of a dog is removed during chloroform anesthesia, the laryngeal muscles retain their ability to contract for a short period, which varies from 3 to 10 minutes, but no contraction can be produced in the muscles of a dead larynx, even if it is removed immediately after the death of the animal, because the arterial blood has escaped. In order to produce the vibrations the current of air should be impelled by a pressure of from 6 to 8 inches of water as it is in the normal production of the human voice. In these conditions the excised larynx of the dog barks and howls in every note of the canine register from the deep baying of a mastiff to the shrill pipe of a terrier. These various notes are obtained at will by causing various muscles to contract. If the stimulation is confined to the muscles which connect the two arytenoid cartilages (two small cartilages at the back of the larynx to which the posterior ends of the vocal cords are attached) these cartilages approach each other and a deep tone is produced. If, on the other hand, the stimulation is extended to the muscles which connect the arytenoid cartilages with the thyroid cartilage (the large V shaped cartilage at the front of the larynx, constituting the 'Adam's apple,' to which the anterior ends of the vocal cords are attached) the vocal cords are contracted and a high, shrill note results.

The pitch of the note appears to be independent of the pressure of the air and the strength of the electric current, and to be determined solely by the part of the muscular system of the larynx to which the stimulation is applied. The whole larynx, including the glottis and the epiglottis, changes its form with every change in pitch. Hence the larynx is a musical instrument which produces various notes by changing its form and dimensions.

These experiments, in addition to their purely scientific interest, explain the sudden loss of voice to which singers and public speakers are often subject. The loss of voice has nothing to do with the vocal cords, but is caused by a sudden contraction of some of the muscles which control the glottis and is analogous to the rheumatic and neuralgic pains which appear suddenly in various parts of the body.

## BERNARD PALISSY, THE FAMOUS FRENCH POTTER, AND HIS WORKS

(Continued from page 125.)

tilizer, etc., that modern scientific research has proved to be correct. He was arrested as a heretic in 1588 and immured in the Bastile, but in 1590, before his case had been disposed of, he died.

Quite a number of authentic specimens of his work are in existence, and they are practically as priceless in value as they are superb in execution. At the Louvre and Cluny Museums, from which our illustrations are obtained,

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. **In every case it is necessary to give the number of the inquiry.** Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO. Inc.

## BUSINESS OPPORTUNITIES

TO INVENTORS. New ideas developed into commercial shape by expert engineers. Mechanical Development & Construction Co. Room 27, 126 Liberty Street, New York.

**Inquiry No. 8918.** For manufacturers of "Wyeth's Electro Catalytic Sparking Plug."

FREE FACTORY SITES at Ooltewah, near Chattanooga. Good railway facilities, low freights. Steam coal costs $2 ton at Ooltewah. No snow last winter. Board of Trade Ooltewah, Tenn.

**Inquiry No. 8997.** —Wanted the manufacturers of the Van Winkle Woods & Sons and the Waber power motors.

## FOR SALE

FOR SALE.—Engine lathe, swings 9¼ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads, 4 to 40 in. Price only $40.00. Address L. F. Grammes & Sons, Allentown, Pa.

**Inquiry No. 9014.** —For manufacturers of machinery supplies etc. to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

FOR SALE or on royalty. Patent No. 941,882. Flush Door Hangers, granted August 17, 1909. Full particulars on request. Address Geo. Fristad, Kenmare, N. D.

**Inquiry No. 9016.** Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

FOR SALE.—Patented in U. S. A., also intention in Canada, Broom Hanger, No. 987,296. Will sell outright for $800, or on royalty. Will manuf. with a partner with capital. Jas. H. Ashmead, Lake George, N. Y.

## WANTED.

WANTED, by a large corporation, several bright college men. First-class chemists, physicists preferred. Good opportunities and excellent salaries to right men. Address Opportunity, Box 773, New York.

**Inquiry No. 9023.** Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

WANTED.—Inventor with common sense ideas wants financial backing. Must be on the square and have sufficient capital to build and operate factory. Address Invest, 120 South 5th Street, Fremont, Ohio.

**Inquiry No. 9030.** Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

WANTED party to undertake the selling of my patent for an automatic railway switch. A firm holder specially for street and industry. Address G. Lange, 904 Garden Street, Hoboken, N. J.

**Inquiry No. 9036.** —Wanted, the address of the manufacturers of "Cycle Ball Bearing Suspenders."

## MISCELLANEOUS

PUBLIC LAND IN OREGON.—Write for free booklet "Millions of Acres Public Land Given Away in Oregon. When, how, where." Douglas County Abstract Co., Roseburg, Ore.

**Inquiry No. 9038.** —Wanted, the address of the Chipman Electric Purifying Co.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

**Inquiry No. 9042.** —Wanted the address of Farney Safety Razor Co.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

**Inquiry No. 9046.** Wanted, machinery used for the manufacture of all kinds of fruit boxes, baskets and crates.

**Inquiry No. 9049.** Wanted to buy rotary brushes suitable for a shoe shining machine.

**Inquiry No. 9053.** —Wanted, address of firms who install plants to manufacture nitrogen.

**Inquiry No. 9055.** —Wanted address of parties interested in Log Cleaning Machines.

**Inquiry No. 9057.** For manufacturers of glass and china balls, used as fixtures or ornaments on lightning rod equipment, also weather vanes for same purpose.

**Inquiry No. 9058.** —Wanted firms who make machinery used for pulverizing soap-stone.

**Inquiry No. 9060.** Wanted to buy machinery to manufacture seed corn racks.

**Inquiry No. 9062.** Wanted to buy a plant for manufacturing muriatic acid.

**Inquiry No. 9065.** —Wanted to buy a second hand telephone generator.

**Inquiry No. 9066.** —Wanted complete outfit for export for making rice-flakes and wheat-flakes.

**Inquiry No. 9067.** —Wanted the address of makers of the Standard Folding Typewriter.

**Inquiry No. 9068.** —Wanted to buy machinery for manufacturing chewing gum such as rolling, cutting or wrapping machinery.

**Inquiry No. 9069.** —For the address of firms making chain cloth, something like ladies' purses are made of.

**Inquiry No. 9070.** —Wanted manufacturers of metal castings for art lamp shades.

**Inquiry No. 9071.** —Wanted the address of parties making moulds for large concrete vases for flower pots.

**Inquiry No. 9072.** Wanted, machinery for making fine chains, such as used by jewelers, etc.

**Inquiry No. 9073.** —Wanted, machinery to manufacture cocoanut oil; also the crude material.

**Inquiry No. 9074.** —Wanted to buy old model locomotives or steamboats, such as were exhibited with nickel-in-the-slot attachments in ferry houses, etc.

Cycles, apparatus for utilizing the force of the wind for propelling, J. Cruder 947,731
Damper clip, C. D. Wagner 947,505
Desk, J. A. Kennedy 947,734

Lumber sheet, built up, G. A. Wright 947,[illegible]

## Home-Made Experimental Apparatus

In addition to the following articles, the Scientific American Supplement has published innumerable papers of immense practical value of which over 17,000 are listed in a carefully prepared catalogue, which will be sent free of charge to any address. Copies of the Scientific American Supplement cost 10 cents each.

If there is any scientific, mechanical, or engineering subject on which special information is desired, some papers will be found in this catalogue in which it is fully discussed by competent authority.

A few of the many valuable articles on the making of experimental apparatus at home are given in the following list:

ELECTRIC LIGHTING FOR AMATEURS. The article tells how a small and simple experimental installation can be set up at home. Scientific American Supplement 1551.

AN ELECTRIC CHIME AND HOW IT MAY BE CONSTRUCTED AT HOME, is described in Scientific American Supplement 1566.

THE CONSTRUCTION OF AN ELECTRIC THERMOSTAT is explained in Scientific American Supplement 1566.

HOW TO MAKE A 100-MILE WIRELESS TELEGRAPH OUTFIT is told by A. Frederick Collins in Scientific American Supplement 1605.

A SIMPLE TRANSFORMER FOR AMATEUR'S USE is so plainly described in Scientific American Supplement 1572 that anyone can make it.

A ⅛-H. P. ALTERNATING CURRENT DYNAMO. Scientific American Supplement 1558.

THE CONSTRUCTION OF A SIMPLE PHOTOGRAPHIC AND MICRO-PHOTOGRAPHIC APPARATUS is simply explained in Scientific American Supplement 1574.

A SIMPLE CAMERA-SHUTTER MADE OUT OF A PASTEBOARD BOX, PINS, AND A RUBBER BAND is the subject of an article in Scientific American Supplement 1578.

HOW TO MAKE AN AEROPLANE OR GLIDING MACHINE is explained in Scientific American Supplement 1580, with working drawings.

EXPERIMENTS WITH A LAMP CHIMNEY. In this article it is shown how a lamp chimney may serve to indicate the pressure in the interior of a liquid, to explain the meaning of capillary elevation and depression, to serve as a hydraulic tourniquet, an aspirator and intermittent siphon, to demonstrate the ascent of liquids in exhaustive tubes, to illustrate the phenomena of the bursting bladder and of the expansive force of gases. Scientific American Supplement 1583.

HOW A TANGENT GALVANOMETER CAN BE USED FOR MAKING ELECTRICAL MEASUREMENTS is described in Scientific American Supplement 1594.

THE CONSTRUCTION OF AN INDEPENDENT INTERRUPTER. Clear diagrams giving actual dimensions are published. Scientific American Supplement 1615.

AN EASILY MADE HIGH FREQUENCY APPARATUS WHICH CAN BE USED TO OBTAIN EITHER D'ARSONVAL OR OUDIN CURRENTS is described in Scientific American Supplement 1618. A plunge battery of six cells, a two-inch spark induction coil, a pair of one-pint Leyden jars, and an inductance coil, and all the apparatus required, most of which can be made at home.

SIMPLE WIRELESS TELEGRAPH SYSTEMS are described in Scientific American Supplements 1363 and 1381.

THE LOCATION AND ERECTION OF A 100-MILE WIRELESS TELEGRAPH STATION is clearly explained with the help of diagrams in Scientific American Supplement 1622.

THE INSTALLATION AND ADJUSTMENT OF A 100-MILE WIRELESS TELEGRAPH OUTFIT, illustrated with diagrams, Scientific American Supplement 1623.

THE MAKING AND THE USING OF A WIRELESS TELEGRAPH TUNING DEVICE, illustrated with diagrams, Scientific American Supplement 1624.

HOW TO MAKE A MAGIC LANTERN, Scientific American Supplement 1546.

THE CONSTRUCTION OF AN EDDY KITE. Scientific American Supplement 1555.

THE DEMAGNETIZATION OF A WATCH is thoroughly described in Scientific American Supplement 1561.

HOW A CALORIC OR HOT AIR ENGINE CAN BE MADE AT HOME is well explained with the help of illustrations, in Scientific American Supplement 1573.

THE MAKING OF A RHEOSTAT is outlined in Scientific American Supplement 1594.

Good articles on SMALL WATER MOTORS are contained in Scientific American Supplement 1494, 1049, and 1066.

HOW AN ELECTRIC OVEN CAN BE MADE is explained in Scientific American Supplement 1472.

THE BUILDING OF A STORAGE BATTERY is described in Scientific American Supplement 1433.

A SEWING-MACHINE MOTOR OF SIMPLE DESIGN is described in Scientific American Supplement 1210.

A WHEATSTONE BRIDGE, Scientific American Supplement 1595.

Good articles on INDUCTION COILS are contained in Scientific American Supplements 1514, 1522, and 1527. Full details are given so that the coils can readily be made by anyone.

HOW TO MAKE A TELEPHONE is described in Scientific American Supplement 966.

A MODEL STEAM ENGINE is thoroughly described in Scientific American Supplement, 1527.

HOW TO MAKE A THERMOSTAT is explained in Scientific American Supplements 1561, 1566, and 1466.

ANEROID BAROMETERS, Scientific American Supplements 1500 and 1554.

A WATER BATH, Scientific American Supplement 1464.

A CHEAP LATHE UPON WHICH MUCH VALUABLE WORK CAN BE DONE forms the subject of an article contained in Scientific American Supplement 1562.

Each number of the Scientific American Supplement costs 10 cents by mail.

(Concluded from page 133.)

be is very completely represented by important specimens showing the three distinct styles that he adopted in the course of the development of his art. His first dishes were usually oval in form, decorated in the center and at the edges with animals, modeled after nature, fish, frogs, snakes, shells and shell-fish, reposing on flowered moss, or swimming in streams of transparent water; at the back enamel marbled in yellow, green, and red. In his second style Palissy partly abandoned the rustic decoration of his pieces, he retained only the shells as a framing and gave to the central subject the chief importance. Finally, in his third style, he abandoned the rustic completely and used only the marbled enamel as a poly-chrome attraction. The modeled figures then became very important and sometimes he reproduced, in poly-chrome pottery, the pewter vessels of the then celebrated Briot, such as the famous piece which represents the "triumph of temperance," of which an illustration is here presented, and he modeled in miniature sculpture and afterward colored and enameled a very diversified series of small articles, nurses, hurdy-gurdy and bagpipe players, etc.

We produce herewith a portrait of Bernard Palissy from an old French miniature of his period on vellum, that is preserved at the Cluny Museum. Palissy is represented, full face and in court costume with ruffs. His doublet is embroidered and relieved with gold, the sleeves are be-ribboned, and on the chest is braid. Above the head appears the inscription B. Palissy.

His works reflect alike genius and artistic taste, and his work was original, marvelously true to nature in execution and coloring, and probably in a more marked degree than any other master of the ceramic art, he learned to perfect colors that would be, after firing known quantities, a knowledge that enabled him to duplicate, with such wonderful certainty, the color effects of the fish, reptiles, insects, etc., he loved to reproduce. The extent to which his style was imitated affords the most practical proof of the favor it enjoyed.

### An Electro-pneumatic Conveyor System for Libraries.

An electro-pneumatic system is used in the Berlin royal library for carrying out the distribution of books to the readers. Upon this system the reader fills out a blank containing the name of the desired book, and upon this blank an employee writes an exact indication of the place where such volume is to be found. The bulletin is then sent by pneumatic tube to the central office. This office is directly connected by elevators with the different stories of the building. These elevators are of small size and are operated electrically on a push-button system. Besides, there is a large elevator running through all the floors for transporting persons and books. A set of pneumatic tubes also run from the central office to the different floors which contain the books. The employee of the central office who receives the reader's bulletin sends the same by pneumatic tube to the proper floor, and on this floor the attendants read the sheet and bring the desired books to the elevator which takes them to the central office. The latter office then sends the books to the point from which the bulletin was sent in the first place, either in the main reading room or any other of the rooms of the library.

Writing to Stahl and Eisen, a German manufacturer states that he has succeeded in making satisfactory high-speed steels with powdered ferro-tungsten. The steel contains 0.85 of tungsten, 0.45 silicon, 0.45 manganese, 0.80 carbon, 0.35 aluminium, calcium, and magnesium, and 0.01 of sulphur. The powdered ferro-tungsten alloys more readily than tungsten metal, and there is less segregation and piping.

# Hartford Fire Insurance Co.

With the coming of 1910, THE HARTFORD FIRE INSURANCE COMPANY has rounded out a century of business history. That means something in the hazardous business of fire insurance, for four out of every five companies organized in this country have either failed or retired. It means unshaken stability. The smoke of every great American conflagration has darkened the sky over the Hartford's head. In San Francisco alone it paid ten millions. But emerging triumphant from the ordeals of 100 years, it enters its second century stronger than ever.

Unshaken stability for a century is no mean heritage, but age is venerable only when adorned with honor. Honor implies more than honesty. It is the quality which impels an institution to meet every obligation, not only with promptness and exactness, but with fairness and a spirit of equity. That is the Hartford's record in the past, its aim today, and its ideal for the future. Its policies afford unsurpassed indemnity, and by co-operating with its patrons to lessen fire dangers, it offers continuous service. Its business, scattered among more than 15,000 communities throughout this great land, is the largest of any fire insurance company in America. Its agents are everywhere.

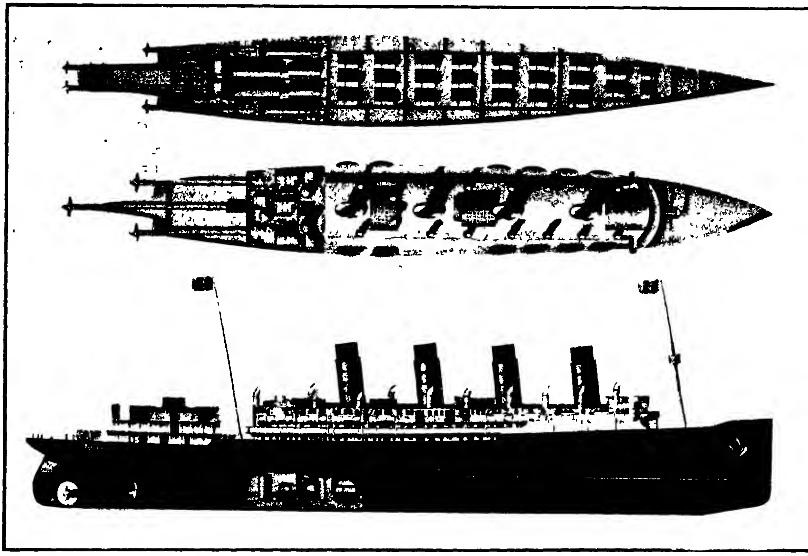
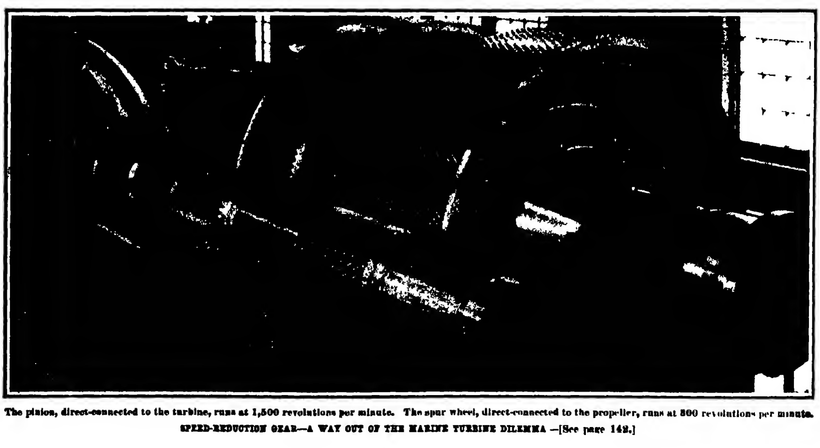
ESTABLISHED 1845.

NEW YORK, FEBRUARY 12, 1910

10 CENTS A COPY
$3.00 A YEAR



The upper engraving shows the space occupied by the boilers and engines of the "Mauretania." The two lower engravings demonstrate the large saving in space resulting from the use of high-speed turbines, driving, through reduction gears, three slow-speed propellers. They would save 1,600 tons of coal and over $5,200 on each transatlantic trip



The pinion, direct-connected to the turbine, runs at 1,500 revolutions per minute. The spur wheel, direct-connected to the propeller, runs at 800 revolutions per minute.

SPEED-REDUCTION GEAR—A WAY OUT OF THE MARINE TURBINE DILEMMA.—[See page 142.]

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## CANADA AND THE QUEBEC BRIDGE.

ENGINEERING and architectural works of the first magnitude are to no little degree an expression in concrete form of the character of the people by whom they are built. It would be difficult to define the extent to which our impressions of the ancient Greek are based upon the architecture of his noble shrines and temples, or how far our respect for the later Roman is due to feats of engineering skill that would do credit to our twentieth century civilization.

Because of the skill and daring which are or seem to be involved, the design and erection of bridges of unusual magnitude has ever been considered one of the most difficult, we had almost said spectacular, feats of construction; and the successful erection of such structures has brought world-wide fame to the engineer and distinct national credit to the country in which the work was done. Thus the Forth Bridge stands to-day as one of the noblest monuments of constructive engineering in the whole of the British empire, and a memorial to the man who was responsible for the design has recently been placed in Westminster Abbey. So too our own beautiful and dignified Brooklyn Bridge over the East River is a lasting tribute to bridge engineering as individualized in America, and the city of Trenton has recently unveiled a monument to the memory of Roebling, the father of long-span suspension bridges.

But that selfsame notoriety which brings international fame to the man and the people who carry great engineering works to a successful issue must, in the very nature of things, throw a proportionate shadow of discredit when one of these great structures falls in utter ruin and, as in the case of the Quebec Bridge, carries nigh upon one hundred souls to destruction. This fact was frankly recognized at the time by the engineering and technical press both in this country and in Canada, and it was realized to be a matter of national importance that when the bridge came to be rebuilt, the new structure should not only be perfectly stiff and strong, but that it should embody such architectural treatment as would render it æsthetically pleasing to the eye, and worthy of that great school of bridge engineering which has sprung up and flourished in the Western Hemisphere.

When the Canadian government took hold of the matter and lent all its powerful prestige and financial assistance to the scheme, it was accepted as an augury that the new bridge would be worthy of the great Dominion across the border line. We have to confess, however, that the bridge which it is now proposed to build is decidedly disappointing. The type selected and the method of treatment are not up to the latest standards of bridge engineering. In other words, the design is distinctly commonplace. Æsthetically it has not a single redeeming feature.

In redesigning the bridge, the Canadian government could have made more sure of securing the best possible designs, if they had thrown the bridge open to world-wide competition. We should then have learned whether the strongest, most economical and most beautiful bridge could have been secured under the cantilever or under the suspension system of design. Personally, we believe that on all three counts it would be possible to produce a suspension bridge that would be greatly superior to the structure which it is now proposed to build. The suspension bridge, especially when built of these great proportions, is a far easier bridge to erect, not being subjected to those heavy erection stresses which are the peril of large cantilever erection. Moreover, the essential elements, namely, the anchorages, the towers, and the main cables, are at all times entirely free from suspicion, and may be erected with the absolute certainty that they are well within the limits of safe construction. With these main elements assured, it is possible for failures to occur in subordinate elements, such as the suspenders and stiffening trusses, without in the least endangering the integrity of the bridge as a whole.

Not so, however, the cantilever bridge, the greater part of whose intricate framework is in compression. Let but one among the multitudinous members of the main trusses fail, and the whole structure will be thrown into immediate and absolute ruin—as witness the mass of tangled steel now lying in the St. Lawrence River.

For the credit of the profession of bridge engineering in the New World, for the prestige of the great and growing people of Canada, and above all for the greater safety of the public at large, we trust that, before the final plans of this great bridge are adopted, the Canadian government will take steps to make it certain that the final bridge will, from every point of view—engineering, architectural, and artistic—be the noblest work of its kind yet erected in any country.

## CAUSES OF THE PARIS FLOOD.

THERE appears to be a consensus of opinion among the French scientists that the causes of the recent phenomenal rise of the Seine, when it reached the record height of 31 feet 2 inches, are to be found more in geological than in meteorological conditions. The basin of the Seine and the streams that are tributary to that river consists of a light absorbent soil, and, as the slopes are gentle, any sudden precipitation is ordinarily absorbed by the ground. In winter, when the soil is either frozen or saturated by the rains, there is a risk that the run-off of a heavy precipitation will be so large and sudden as to overtax the capacity of the river channels. These conditions obtained to a marked degree during the recent continuous heavy rainfall and flood. Meunier, the geologist, is of the opinion that the heavy rains preceding the flood found the soil of the Seine watershed so thoroughly impermeable because of saturation that the water ran off as swiftly as it would from the surface of an asphalted or cemented street. Furthermore, it seems to be generally agreed that the denudation of the forests in the higher regions of the watershed has been a contributory cause to the flood. Not only do the trees assist evaporation, but the forest undergrowth also exerts a material influence in retarding the flow of the water.

Referring again to the question of the prevention of future floods at Paris, regarding which we made editorial comment last week, there is an alternative plan to that of dredging or widening the channel and the removal of river piers which, were it not for the enormous expense involved, would afford an absolute safeguard against future disaster. We refer to the heroic measures employed by the Austrian engineers to prevent the flooding of the city of Vienna by the river Danube. This consisted in cutting an artificial channel entirely around the city through which, after the river reaches a certain elevation, all the surplus waters are diverted and discharged into the river below the city. It would be possible to create a similar by-pass around the city of Paris, but the cost, due to the great value of the land which would have to be condemned, would probably be found to be prohibitive.

## WATER CONSERVATION IN NEW YORK STATE.

AFTER about three years of investigation of the subject of water resources, the State Water Supply Commission estimates that 1,500,000 horse-power of water energy is running to waste every year in the State of New York, and that if this were developed according to plans drawn up by its engineers the State would realize a yearly rental of at least $15,000,000.

As a result of its investigation of the watersheds of the Hudson, Genesee, and Raquette rivers, the Commission has located and surveyed four reservoir projects for the development of water power and the control of floods. These are the Sacandaga and Schroon Lake reservoirs on the Hudson, the Portage reservoir on the Genesee, and the Tupper Lake reservoir on the Raquette. The Commission considers that the Hudson River, because of its size and the large population and important industries of the cities situated along its banks, should receive the first consideration in any system of conservation that may be adopted, and it recommends the construction at a point on the Sacandaga River, 50 miles north of Albany, of a dam and storage reservoir of 29 billion cubic feet capacity. Such a dam would convert 30 miles of the present river valley into an artificial lake of the size of Lake George.

The principal object of this reservoir would be to hold back and store the flood waters, and afford relief during the low-water conditions of the summer to the various power plants along the Hudson, by releasing sufficient water to maintain the level of the river at the desired stage for operation of the hydraulic plants. In addition to the great benefits afforded by such control of the stage of the river water, the power developed directly in connection with the big dam would be transmitted electrically to such towns as Albany, Troy, Mechanicsville, Glens Falls, Utica, Schenectady, and other less important communities lying within the zone of economical electrical transmission. It is estimated that the reservoir would cost $4,650,000, that the total yearly fixed charges and maintenance would amount to $237,700, and the annual gross earnings $427,500, leaving an estimated annual net revenue to the State of $189,800. The Commission estimates that on this basis the cost of the reservoir would be refunded to the State in fifty years, at the end of which time it would be the sole owner of the works, which would yield a perpetual income from the sale of the stored up water.

The Commission advises that the work be undertaken by the State, because under State control the necessary funds can be provided more economically, and the interests of the public can be absolutely safeguarded. It recommends the enactment of a law authorizing the development of the power of the Hudson River, the construction of a storage dam on the Sacandaga at Conklingville, the amendment of the Constitution to permit the flooding of State lands in building storage reservoirs to be owned by the State, another amendment providing for a bond issue to meet the expense of building reservoirs, and the building of other reservoirs to regulate the flow of rivers for power purposes and flood control.

## STEEL BELTS.

IN Germany steel belts are used in many large factories and electric power stations. The principal difficulty connected with their employment is that of joining the ends of the belt. These ends are now provided by the makers with steel plates which need simply to be screwed together. It is necessary to use steel of special quality and temper. It is advantageous to cover the belt wheels with coarse canvas, to which thin slices of cork are attached, in order to prevent slipping. The cork lasts practically forever and reduces the sliding to less than one tenth per cent of the travel. Prof. Kammerer has experimented with a steel strap, two-fifths inch wide and one-fiftieth inch thick, with two wheels, eight feet in diameter, for the transmission of 16 horse-power with a tension of 440 pounds. Although the wheels were not covered, they worked very silently even at a speed of 200 feet per second. The maximum slipping was one per cent of the travel and the loss of energy due to this cause was inappreciable.

Steel belts possess the following advantages: The energy is transmitted without slipping and almost without loss, the belts do not stretch, their width may be reduced to between one-third and one tenth of that of leather belts transmitting the same power, consequently the wheels may be narrower and lighter and the workshop less darkened by them. The steel belts do not deteriorate appreciably; they may be used in damp places and do not appear to be attacked by smoke or acid. They allow the attainment of velocities of 100 feet per second and are consequently very suitable for use with turbines. The required tension is one-tenth less than that of leather belts transmitting the same power, because of the difference in weight, from which results an additional economy, owing to the diminished friction on the bearings. Much room can be saved by using steel belts because their efficiency does not depend upon their length. They can be used horizontally in place of gearing. The makers assert that they cost less than leather belts of good quality.

The oldest steel belts have been in service two years. In a Berlin factory a leather belt 24 inches wide was replaced by a steel belt 4 inches wide which transmits about 250 horse-power. The belt, after two years' use, shows no indication of wear. The only objection to steel belts is that they are not easily seen, and consequently may cause accidents if they are not carefully guarded.

---

**A remarkable phenomenon was observed during a thunder shower in Finland in the summer of 1908 by V. J. Laine, who was making meteorological observations for the Finnish scientific society. The shower approached from the east and the thunder, which had been heard at intervals during a half hour, ceased before any rain fell at the place of observation. During approximately the same half hour the eastern horizon was completely spanned by a double rainbow, which likewise vanished before the rain came. Immediately after each peal of thunder the colors of both bows and especially those of the secondary bow, became confused and indistinct, and the whole double rainbow appeared to vibrate rapidly. Laine explains this singular phenomenon, in accordance with the Airy-Pernter theory of the rainbow, by assuming that the concussion of the air which produced the sound of thunder, also increased the diameter of the rain drops from less than 1/250 inch to between 1/50 and 1/25 inch. If this assumption is confirmed it will furnish a valuable contribution to the theory of thunder storms, which is still incomplete.**

## ENGINEERING.

According to a recent dispatch, a contract for the construction, at a cost of $500,000, of a dam which will form part of an irrigation scheme in the southern section of the island of Porto Rico, has been awarded to native engineers, who secured the award in competition with four American firms. The total cost of the scheme is $3,000,000.

The heaviest rainfall ever recorded for a single day on the Isthmus of Panama occurred during the great flood of last December, between the hours of 10 A. M December 28th and 10 A. M December 29th, when the rain gage at Porto Bello showed a fall of 10.86 inches. The total fall for the month was 58 17 inches, which is equal to an average rate of nearly two inches a day

The stern frame, rudder, and brackets for the new White Star liner "Olympic," which were recently supplied by the Darlington Forge Company, are the heaviest ever cast for a steamship Their total weight is 289 tons, made up as follows Stern frame, 70 tons, after boss arms, 74 tons, forward boss arms, 45 tons, and rudder, 100 tons The total weight of the same parts as cast for the "Mauretania" was 220 tons.

The rapid elimination of the sailing vessel is shown by statistics recently given by a German paper In the twenty years between 1888 and 1908 the percentage of sailing vessels has declined in the merchant marine of Great Britain from 44 1 to 12 6, of Germany, from 62.1 to 19 1, of the United States, from 80 7 to 30 9 In the merchant marine of France, however, but little change has occurred, the respective percentages being 47 9 and 47 2

According to the French paper Matin, the Minister of Marine is asking for the construction of two dreadnoughts of 23,000 tons each in a programme which has been recently submitted to Parliament, and he has sanctioned the arrangement of turrets adopted by the Superior Council of the Navy, which recommended two turrets containing three guns and three turrets with two guns. There will be eighteen unusually powerful guns in the secondary battery, and the speed is to be twenty knots.

The locomotive recently built for the electric operation of trains through the Cascade tunnel of the Great Northern Railway, where the electrical equipment extends for about six miles, weighs about 120 tons and is furnished with four 3-phase 400-horse-power motors working on a 500-volt, 25-cycle circuit The pressure on the line is 6,000 volts, which is reduced by transformers carried on the locomotive. The power plant, which is driven by water power, has sufficient capacity for the operation of sixty miles of the line

The Public Service Commission has recently adopted an order requiring the New York Subway operating company to install on all subway cars destination signs, similar to those now used on some of the cars of each train The company must also post in all stations, near the ticket office, a map showing the locations of its routes and the streets intersecting the subway line; and all stations must be equipped with illuminated signs, placed on the subway walls, for the purpose of warning passengers that they are approaching the station

It is claimed that the lighthouse establishment of the United States government is the most complete and efficient in the world On June 30th, 1909, the service included no less than 1,643 lighthouse keepers; and during the fiscal year of 1910, 61 additional lights, requiring the services of 47 keepers, will be established Legislation is being sought for the establishment of three additional lighthouse districts, covering Alaska, Porto Rico and the naval station at Guantanamo, and the Hawaiian Islands. The cost of the establishment last year was $5,357,000

In a recent communication to a New York paper, Mr Hudson Maxim shows the futility of attempting to work any serious destruction by the dropping of dynamite from a flying machine. He states that the destruction effected would be very much less than anyone not acquainted with the action of high explosives would suppose; and that many tons of dynamite might be exploded in the middle of Madison Square without any more serious damage than the blowing out of the windows of adjacent buildings by the rush of air toward the explosion to fill the void formed by the uprush of the heated gases and air.

A word of warning has recently been given by J N Bailey, an English engineer, to those who are contemplating an increase of their power plant by utilizing the exhaust steam of reciprocating engines in a low-pressure turbine. He states that there are cases in which a positive loss would occur if the exhaust steam were used in a turbine in preference to a feed-water heater. In one installation which came under his notice, the major part of the latent heat in the steam, which had been used efficiently in the feed heater, was wasted in the condenser into which the turbine exhausted; for, while some 86 per cent of the heat from the steam could be utilized in the feed heater, only about 5½ per cent was recovered in the turbine.

## ELECTRICITY.

Less than a year ago the New York Public Service Commission of the Second District issued an order limiting the number of passengers that could be carried on each car of the Pine Hills line in Albany There was so much public dissatisfaction with this restriction that the order has recently been withdrawn.

A report on the tie and pole consumption in 1908 has recently been issued by the Census Bureau. The total number of ties purchased by electric railways for the year was 6,425,368, of which 4,592,195 were hewn and the rest sawed. A large majority of the ties were oak, the number being 2,414,403, chestnut comes second with 1,282,128, while Southern pine and cedar follow with 944,690 and 850,687 respectively The number of poles bought by electric railways and electric light and power companies was 531,497, which is considerably less than the number for the previous year The majority of the poles were cedar, viz., 285,689, chestnut comes second with 166,050

In place of the ordinary windmill type of tower hitherto used for transmission lines, a new form of tower is now beginning to find favor It consists of two columns spaced a short distance apart and connected by horizontal members The plane of the tower is transverse to the direction of the line, and at its upper end it supports a cross arm on which the transmission lines are supported The advantage of this construction over the rigid windmill type is the fact that in case of a break in the line each tower would give somewhat and distribute the strain, thus preventing the towers from being pulled over one after the other

The Illinois traction system covers a territory 90 miles wide and 225 miles long Much new work is being done along the lines of this system which requires the general manager to make frequent trips from place to place To prevent loss of time he has had a sleeper and office car built, in which he can conduct business while *en route* and which will carry him over night from one point to another The manager's car is well equipped with all the conveniences that he might desire on his trip It is provided in the forward part with an office room so arranged that it can be converted into a bedroom with four berths separately curtained off In addition to this there is a dining room and kitchen The over-all length of the car is 62 feet.

In the recent report of the Royal Commission on Canals and Inland Navigation of the United Kingdom, the following conclusions are reached on the question of electric haulage on canals, namely that a greater regularity and uniformity of speed may be maintained, that there will be less erosion of the canal banks from waves, that there will be an economy in the size of the locks because the storage capacity of barges is not taken up with propelling machinery as in tugs and steamboats, and that the electric power can be utilized for operating the locks and even for factories along the canal The experiment was made in France not long ago of providing for horse and electric haulage side by side, but this proved to be inexpedient because the electric traction was constantly retarded by the slower horse-drawn boats.

One of the exhibits at the recent Chicago Electrical Show, which attracted considerable attention, was the government aeroplane fitted with a wireless telegraph receiving and sending system The chief difficulty in fitting up an aeroplane for wireless telegraphy lies in the fact that it is strung with wires used for bracing the parts and these interfere with the reception of the message on the short antennæ available on such a machine The difficulty was overcome by stringing three strands of No. 14 copper wire along the under surface of the upper plane and connecting these strands with a loop of wire strung about the runners of the aeroplane. Conditions in the Coliseum were not such as to permit of demonstrating the advantages of such a system of antennæ, but nevertheless it was possible to carry on telegraphic communication between the aeroplane and a station in the annex of the Coliseum.

A novel proposition was presented before the recent meeting of the American Institute of Electric Engineers by Prof. W S Franklin and Mr S. S. Seyfert. They propose to reduce the length of single-phase series motors, so that motors of higher horse-power can be accommodated in the space between the drivers of a locomotive The reduction of length is effected by using a stationary exterior armature and a revolving field and removing the commutator to any convenient point. The commutator would be stationary and the brushes would have to be revolved about it by connection with the field This would provide more space for the armature windings, which in this type of motor should be stronger than the field, and would enable a better utilization of the space ordinarily occupied by the commutator The advantage of having the commutator accessible and constantly in view would offset the mechanical disadvantages of separately revolving the commutator brushes.

## SCIENCE.

Count Plunkett, the Director of the National Museum of Science and Art, Dublin (Ireland), has received notice of a bequest of £5,000 to that institution, left by Mr Patrick Murphy of Newry

A crew of eleven map makers of the Geological Survey, under the leadership of Chief Topographer C H Birdseye, are mapping the Hawaiian Islands Their work will occupy all told about eighteen months, by the end of which time it is thought that they will have succeeded in making detailed maps of Kauai, Oahu, Molokai, Mauri, and Hawaii This work is preliminary to a possible extension of the reclamation service of Hawaii

Are the senses ever vicarious? The question is discussed in Nature by Prof McKendrick and by several blind men According to one correspondent the popular notion that when a person loses his sight he is compensated by the gift of ability in one, if not all, of his other faculties, is absurd He points out that the imputation of striking ability does not enable a specially talented blind man to earn his livelihood by the exercise of that ability The blind are credited with powers in music, basket making and the like but when they assert their right to live the ordinary lives of citizens they are not permitted to do so

With the ordinary moving picture machine photographs 2 5 by 1 9 centimeters are taken at about the rate of 16 per second, which is much too slow for taking a picture of a bullet or other projectile in flight Even if the rates were 60 per second no satisfactory results could be obtained In a recent number of the Zeitschrift Instrumentenk, C Cranz describes a ballistic kinematograph apparatus which gives a time interval of 1/5000 of a second so that shot photographs can be readily obtained, and from these the velocity of the shot can be found The pendulum used makes electrical connections at different points of its swing, and these are utilized to obtain the photographs

The last opposition of Mars, although eagerly welcomed by observatories of the world has by no means settled the perennial problem of Martian surface markings Mr Lowell still insists that he sees the canals Prof Ritchey has not succeeded in photographing them, and Antoniadi still doubts the existence of the canals It would seem that the time has come for astronomers to reach some definite agreement and accordingly Mr R G Aitken in a recent number of Science suggests that Mr Lowell should invite two or three students of planetary detail such as E E Barnard, W H Pickering and E M Antoniadi to come to Flagstaff to join him in observing Mars at its next opposition and thus settle once and for all what is really seen at Flagstaff

Commander Peary has placed before the Board of Managers of the National Geographic Society a proposition in behalf of the Peary Arctic Club, to the effect that the Geographic Society join with the Peary Arctic Club in an Antarctic expedition the Arctic Club to furnish as its share of equipment the steamer "Roosevelt," used by Commander Peary on his North Pole trips and the Geographic Society to furnish funds for the other expenses to the amount of $50 000 the expenses above $50,000 to be borne equally by the Geographic Society and the Peary Arctic Club Commander Peary declines to head the expedition himself, believing that the work should be intrusted to younger men Should the plan be carried into execution it is not unlikely that almost all members of the successful Peary North Pole expedition will proceed to the Antarctic in the Roosevelt

Prof. Frank H. Knowlton of the U S Geological Survey, has just published in the Smithsonian Miscellaneous Collections a short paper entitled "Descriptions of Fossil Plants from the Mesozoic and Cenozoic of North America." The paper includes descriptions of two new fossil chain-ferns, the first of which called *Woodwardia maroni*, was found in the Fort Union formation near Rock Springs, Wyoming It is of special interest from the fact that it is very closely related to the common chain fern so widely distributed over eastern North America from Nova Scotia to Ontario and Michigan, and south to Florida Louisiana, and Arkansas The other new species which he names *Woodwardia columbiana* is from the Pleistocene and was found at the Cascades of the Columbia River in Oregon It, likewise, resembles closely a living species originally described from Mexico, but also found in Guatemala Arizona, California, and Washington Prof Knowlton also describes a *Dennstaedtia americana*, which is characteristic of the Fort Union formation, never having been found outside of it This fern has its closest affinity with a living species found widely spread over China, Japan, tropical Asia, Polynesia and Madagascar These three new ferns were found in excellent condition, showing the fructification, and are of special interest on account of their close resemblance to forms now living a very unusual experience with fossil plants.

# A NOVEL AMERICAN MONOPLANE

The monoplane illustrated herewith is one of the most novel aeroplanes which has thus far been produced It is the invention of Mr A. L Pfitzner who for some time past has been associated with Mr Glenn H Curtiss in the production of his aeroplanes

This new monoplane while resembling the Curtiss biplane in some features is a distinct departure from the usual type of single surface machine such as produced abroad by Blériot and the Antoinette Company Unlike these machines there is no square or triangular body extending the length of the machine and carrying a pair of wings near its front end In place of this there is a single plane mounted upon four vertical wood struts at its center and having a fixed horizontal tail 10 feet at the rear and a single surface horizontal rudder 14 feet in front The vertical rudder is placed in front just above and at the center of the horizontal rudder Both rudders are therefore always within the view of the aviator They are controlled by a single wheel placed vertically in front of the aviator This wheel also operates sliding panels on the under side of the monoplane at each end for the purpose of maintaining the transverse stability The fact that all three controls are operated by a single wheel makes this machine the simplest to drive of any thus far produced

The plane has a spread of 30 feet and a fore and aft width of 6 feet The plane itself is but 31 feet x 6 feet equivalent to an area of 186 square feet The sliding wing tips are each 2½ feet by feet from front to rear The horizontal rudder is 6 x 3 feet in size and the vertical rudder 3 feet long by 2 feet high The dimensions of the tail surface are 6 x 2 feet The total weight of the machine the tanks being filled with 6 gallons of gasoline and 1 gallon of oil and the radiator with 1½ gallons of water is 430 pounds The weight carried per square foot is therefore slightly more than 3 pounds

The four vertical posts forming the chassis terminate in forks of seamless steel tubing each of which carries a 20-inch pneumatic-tired wheel The posts are spaced apart by steel tubing braces and by wooden skids extending from the front to the rear The front edge of the main plane is mounted upon these uprights 46 inches above the ground The rear edge which is formed of steel cables stretched over the ribs is 10¼ inches lower than the front edge where it crosses the main vertical uprights The ribs have a slight curvature of about 1 in 19 the camber being 3¾ inches in the length of 6 feet The center of pressure is located about 18 inches back of the front edge of the plane The ribs are laid upon two main spars running the entire length of the machine the foremost of which forms the front edge of the plane while the rear one is 10 inches in advance of the rear edge and rests in sheet steel sockets attached to the heavy main ribs that connect the central vertical uprights At suitable distances from the center of the machine on these front and rear spars vertical struts are attached to them for the purpose of trussing the plane The 25 horse power 4 cylinder 4-cycle Curtiss water-cooled motor is mounted upon two laminated beams extending from a cross tube at the rear through the monoplane surface to the front edge The rear of the motor is substantially braced by four diagonal tubes as can be seen in one of the photographs The propeller especially designed by Mr Pfitzner is 6 feet in diameter and gives 235 pounds thrust at 1 200 R. P M or 9 4 pounds to the horse power The oil tank is seen just below the surface of the plane in the photograph just referred to The oil is cir-

# SMOKELESS POWDER—METHOD OF MANUFACTURE.—II.

BY ROBERT G SKERRETT

In the issue of the Scientific American of February 5th it was shown how greatly the improvements in the power of naval guns are due to the introduction and development of smokeless powder The present article is devoted to the description of its manufacture

The base of our smokeless powder is cellulose—that wonderful and yet indescribable form of matter Cotton is one type of pure cellulose

In 1832 Braconnot discovered that starch dissolved in nitric acid and when cleansed in water became an intense explosive. A little later Pelouse obtained the same results by soaking cotton fabrics in that acid and then washing them in water This was the first step in the evolution of smokeless powder Because of the great violence and erratic behavior of the explosive thus discovered it took years to develop it into a safe propellant More than half a century ago Austria and later Prussia used nitrocellulose in their ordnance but its impetuous action could not then be properly curbed and a series of accidents and unexpected explosions caused its abandonment Years later when the speedy torpedo boat and the rapid fire gun arrived French chemists through stress of need found ways to check the explosive violence of gun cotton and to fashion it into a safe and practical propellant We followed France but our powder has been the immediate offspring of that produced by the great Russian chemist Mendeleff

The nitrating house is like a great, gloomy steam laundry the cotton being digested in centrifugal wringers like those in which clothes are washed

It seems paradoxical that we should seek for a safer and less violent propellant than common gunpowder by adopting for a base an explosive well known to be more vigorous and more unruly The secret discovered by the chemists proved nitrocellulose to be amenable to the influence of deterrent agents which subdue the suddenness of explosion while the form of the grains regulates in a remarkable way the rapidity with which the granules burn and generate the propelling gases Smokeless powder can now be made in grains of such size and such form that the conditions imposed by each caliber of gun can be met and the muzzle velocity of the shot regulated with astonishing precision Thus the task of the ordnance engineer is now quite opposite to that of former days To day the gun is designed to meet certain requirements while the propellant is afterward made to suit the gun

Now for the manner in which harmless cotton is transformed into a ballistic agent at the Naval Powder Factory Indian Head Md No official secrets are betrayed because the value of the process lies in the nice proportioning of the various ingredients combined with particular forms of grains These niceties are the outcome of lessons learned after much experimenting in which the variation of a tiny fraction of an inch may either make or mar the product

Cotton when steeped in nitric acid becomes soluble in a mixture of ether and alcohol if the percentage of nitration be less than 12 75 and is insoluble when the measure of acid is above this arbitrary dividing line When below this percentage nitrated cotton which by nitration becomes an explosive—may be dissolved into a plastic substance and when the ether alcohol solvent has in its turn been evaporated the cellulose becomes a hard tough translucent mass Before hardening however the stuff is pressed into grains of various shapes which burn with a bright orange flame and without smoke Our smokeless powder is a brother of collodion so useful in medicine and the art of photography while celluloid in its endless applications is a first cousin and lies just beyond the dividing line of those substances soluble in ether alcohol

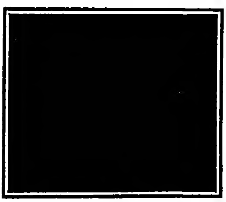
The cotton used may be either the blooms straight from the fields or the white mill waste In either case the cotton is cleansed by an alkaline bath and then well dried in an atmosphere of 212 deg F The workmen toil in this temperature but the perfect dryness of the air explains why they are not boiled alive The object of the drying is to make the cotton more absorptive in the acid thus insuring more nearly perfect nitration After the cotton has been dried it is

The powder is forced through macaroni dies in the form of an endless rope, perforated from end to end with a concentric group of circular passages

packed in airtight canisters and sent to the nitrating house where it is soaked for half an hour in a strong mixture of sulphuric and nitric acids The reaction frees from the cotton a percentage of moisture which if not withdrawn would dilute the nitric acid and affect the character of the product Sulphuric acid has a strong affinity for water and it extracts the moisture thus leaving the nitric acid unimpaired and capable of doing its full work upon the cotton

The nitrating house is not unlike a big steam laun

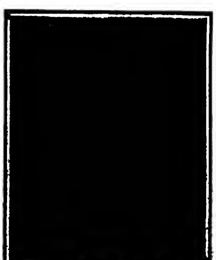
(Continued on page [illegible])



This view shows the important process of washing the cotton in the alkaline bath for the purpose of removing all traces of oil.

The "pyro" is piled into open tubs, and transported to steaming tanks, where it is boiled and boiled to extract the major part of the clinging acid.

Running the fine pulp through the "wet-machine," whence it comes from the rollers in flakes containing about 40 per cent of water



One of the mechanical kneaders in which the "pyro" is mixed with the ether-alcohol solvent, and converted into "colloid," before pressing it into solid cylinders.

The dehydrating house, where all but a very small percentage of the moisture is extracted by pressure and finally by the use of alcohol to drive the dampness before it and leaves enough of the spirits behind to form the needful solvent.

In the drying house, where the powder grains are stored away and dried to the proper stage, before testing and sealing away in air-tight tanks

HOW SMOKELESS POWDER IS MANUFACTURED.

### A WAY OUT OF THE MARINE TURBINE DILEMMA.

Provided that it can be run at the high speed at which its full efficiency can be assured, the steam turbine is the most economical of all steam engines. On land, as a drive, say for electric generators, this high speed of rotation can be employed, since a type of generator may be coupled up that is suitable to that speed. When the steam turbine is employed to drive the propellers of a steamship, it is no longer possible to run it at the best speed for economy, and this for the reason that the propeller at the outward end of the turbine shaft shows its own best efficiency at speeds of rotation far lower than those demanded by the turbine. If we run the shaft at the maximum-efficiency speed of the turbine, there will be a big loss of efficiency at the propeller. If we run the shaft at the maximum-efficiency speed of the propeller, there will be low efficiency in the turbine.

Here we have a dilemma which the marine engineer has hitherto found it impossible to avoid. He has attempted to cut the Gordian knot by a compromise, and has tried to find a mean speed of rotation (too slow for the turbine, too fast for the propeller) which would give the best or rather the least bad results on the "coal per horse-power per hour" basis.

It requires no very keen discernment to perceive that the solution of the problem lies in the selection of some suitable speed-reducing mechanism between turbine and propeller, and as far back as 1904, in a report to George Westinghouse, George W. Melville, the former Engineer in Chief of the Navy, and Mr. John H. MacAlpine, made the following statement: "If one could devise a means of reconciling, in a practical manner, the necessary high speed of revolution of the turbine with the comparatively low rate of revolution required by an efficient propeller, the problem would be solved, and the turbine would practically wipe out the reciprocating engine for the propulsion of ships. The solution of this problem would be a stroke of great genius."

In the intervening years three entirely different methods have been devised for meeting the difficulty. One is to install high-speed turbo-generators, and utilize the current to drive slow-speed motors direct-connected to the propeller shaft, and experimental work in this direction has given such good results that the Fore River Shipbuilding Company recently put in a bid for the equipment of our 26,000-ton battleships with an installation of this character. In another system, known as the hydraulic reduction drive, two hydraulic turbines are interposed between the steam turbine and the propeller, the one connected to the turbine, the other direct-connected to the propeller, with controlling valves between the two which enable the speed to be reduced to any desired extent. For both of these systems it is claimed that high efficiency has been secured. The third method (the one shown in the accompanying illustration) consists in the use of a mechanical reducing gear. During a series of exhaustive tests recently made at the Westinghouse shops, this experimental gear showed the astonishingly small friction loss of one and one-half per cent. These results are far superior to those obtained with the other two methods, and unless some unforeseen disadvantages should develop when the full-size gear comes to be installed on a warship or merchant steamer, it may safely be said that in this reduction gear has been found the final solution of the marine steam turbine problem.

It was no easy task to devise a gearing which would run smoothly and without excessive wear at the high speeds required for steam turbines, and at the same time transmit the thousands of horse-power carried by propeller shafts, which amounts in the case of the "Mauretania" to about 18,000 horse-power per shaft. The experimental gear which is illustrated on the front page of this issue was constructed at the Westinghouse Works at Pittsburg, where it has already undergone, and is still being subjected to, a series of tests. It was realized that if the results were to be convincing the experimental plant must be on a large scale, and the gear was therefore designed to transmit continuously no less than 6,000 horse-power.

As will be seen from the illustrations, the gears are helical; that is to say, they do not run straight across the face of the wheel parallel to the axis, as in the case of ordinary spur gears, but they are cut in the form of a steep spiral. This construction allows the wheels to roll into contact without shock or jar. Of course, this helical form of tooth causes a strong end thrust in the direction of the axis of the shaft, and in order to prevent this, one-half of the gear was cut with the spirals running in one direction and the other half with the spirals in the opposite direction. In this way the end thrust, due to the obliquity of the teeth, is completely balanced.

In spite of the marvelous accuracy with which the teeth of gears can be cut by modern machinery, it is impossible to form them so truly and align the shafts so perfectly as to get an absolutely uniform contact throughout the entire length of the gear. This is an important consideration in all gears, but becomes doubly so when, as in this case, they may have to transmit from ten to twenty thousand horse-power.

The inventors have met the difficulty by a very ingenious construction designated as a floating frame, which they describe as follows: "The frame which carries the bearings for the pinion is a heavy steel casting supported only at a single point midway between the bearings. This support is flexible, so that the frame is free to oscillate in a vertical plane passing through the axis of the pinion, but is held securely against motion in any other direction. Furthermore, the pinion is free to move endwise in its bearings. Any tendency of the teeth to bear harder at one end of the gear than the other would tend to unbalance the respective end thrusts due to the right and left-hand spirals of the teeth, but as the pinion cannot present any resistance to unbalanced end thrust, it constantly adjusts itself in the direction of its axis to the position corresponding to equilibrium between the opposing forces. This means that the tooth contact pressures are always automatically equalized.

"If there are any minute irregularities in the spacing of the teeth, which would tend to make the contact harder at one point than another in any part of the revolution, this tendency is defeated by the floating frame, the position of which about its central support or fulcrum is controlled solely by the pressures of the teeth of the pinion against the teeth of the large gear. Naturally, the floating frame always yields under the slightest tendency of an unbalanced contact pressure, in such a way as to transfer the smallest increment of unbalancing pressure to another section of the gear that, in the absence of the floating frame, would be less inclined to take its full share of the stress. In short, the gears are self-adjusting to relieve and equalize all abnormal strains, and are consequently independent of the small inaccuracies that are impossible to eliminate in the best commercial manufacturing operations."

The gear was tested by means of a special hydraulic brake, the reduction gear being interposed between the turbine and the brake, and in six tests the brake horse-power delivered by the gear at different speeds varied from 3,712 to 5,927. Since there is no way in which to measure the indicated horse-power of a steam turbine, it was necessary to establish the exact brake horse-power in some other way. Fortunately, it is a characteristic of the steam turbine that, as long as the speed and exhaust pressure are maintained constant, the absolute inlet pressure of commercially dry steam is a very accurate measure of the brake horse-power the turbine is developing. Accordingly, a dynamometer, connected directly to the turbine shaft, was substituted for the reduction gear, the turbine was run at a fixed speed, a constant vacuum was maintained in the exhaust pipe, and the inlet pressures corresponding to different loads at this speed were determined. From these tests the following results were obtained:

| B. H. P. delivered by gear | B. H. P. of turbine as determined from inlet press., etc. | Efficiency |
|---|---|---|
| 3,712 | 3,771 | 98.7 |
| 4,156 | 4,197 | 99.0 |
| 4,576 | 4,623 | 98.9 |
| 5,036 | 5,108 | 98.7 |
| 5,486 | 5,567 | 98.5 |
| 5,927 | 6,057 | 98.7 |

A reliable check upon these results is afforded by the rise in temperature of the oil with which the gear is lubricated, since the transmission loss in the gear appears as heat in the oil. By measuring the quantity of oil circulated and noting its rise in temperature, a close approximation to the number of British thermal units lost per hour is obtainable. When the gear was delivering 5,088 horse-power, 591 pounds of oil were circulated, with an average rise in temperature of 9.36 deg. F., from which it follows that the total heat absorbed per hour was 164,205 British thermal units. As 2,545 British thermal units per hour is the equivalent of a horse-power, the total heat accounted for in the oil is 64.17 brake horse-power; and since the total brake horse-power delivered by the gear is 5,088, it follows that the efficiency must be 98.75 per cent. In view of this remarkable coincidence of results, we agree with Mr. H. E. Longwell, the consulting engineer, that the efficiency of the gear is conclusively established as more than 98.5 per cent. The results are, of course, a great surprise and quite unprecedented, but in view of the remarkable adjustability afforded by the floating frame, they are well within reason.

With these results before him, Mr. Westinghouse has made an investigation of the economies which could be secured by applying the gear to the Cunarders "Mauretania" and "Lusitania," which are each capable of developing 70,000 horse-power. If the same high efficiency can be secured on board ship as has been clearly established in the testing room, the results which he arrives at seem to be well founded. It is known that the propeller efficiency in these ships is low, and probably does not exceed 55 per cent. If so, the actual effective propelling power is only about 38,500 horse-power. At the lower speed of revolution resulting from the use of the reduction gear, propellers could be installed that would have an efficiency of not less than 65 per cent; which means that the shaft horse-power required for the same effective propelling power would be less than 57,000—a saving of about 15 per cent. This means that the "Mauretania," without sacrificing her speed of over 26 knots, could reduce the boiler equipment and the coal consumption on each voyage about one-seventh.

But, in addition to this economy at the propeller end of the shaft, there would be corresponding and even greater economies realized at the turbine. For it is well understood that for equal efficiencies in any two turbines the number of rows of blades is, roughly speaking, inversely proportionate to the squares of the respective peripheral speeds of the rotating elements. But the peripheral speed of the rotating elements in the turbines of the "Mauretania" and "Lusitania" is only one-third of the speed common to large turbines used on land. This would mean that to obtain the efficiencies common to the latter, the "Mauretania's" turbines would require approximately nine times as many rows of blades, which would make a machine of prohibitive length. To maintain the same speed of revolution and increase the peripheral speed of the turbines to that of turbines in land practice, the rotors would have to be nearly 40 feet in diameter.

Now, the steam consumption of the turbines of the "Mauretania" is believed to be about 14.5 pounds per shaft horse-power per hour; but it has been proved that in turbines of similar capacity, operating at speeds which the reduction gear makes possible for marine service, the steam consumption does not exceed 11 pounds per shaft horse-power per hour. This means that the boiler capacity, already reduced, as we have seen above, by the increased efficiency of the low-speed propeller, could be further reduced to about 45,000 horse-power, and the total efficiency of the whole installation would result in a reduction of over 35 per cent in the coal consumption. These vessels burn about 4,700 tons per voyage, and since the coal costs about $3.25 per ton, the saving in coal alone would be $5,300 per voyage, to say nothing of the reduced cost for wages, food, etc., for the smaller number of stokers that would be required. A further valuable advantage would be that the reduction of over 1,600 tons in the coal required for each voyage would add that amount to the cargo capacity.

But there are further economies, as will be seen by reference to the illustrations on our front page, which show the space occupied by the present turbine equipment of the "Mauretania" and that necessary if small high-speed turbines combined with reduction gears were employed on three propeller shafts. These remarkable engravings speak for themselves, and further comment is unnecessary.

All the advantages that would result from the employment of this device on merchant steamers would be realized also on naval vessels, together with other collateral advantages due to the fact that the high-speed turbine would not suffer the large drop in economy which results, in the case of the present turbines, when they are operating at cruising speeds. With the superior steam economy of the high-speed turbine the boiler capacity would be reduced fully one-third, and with the same bunker capacity the radius of action would of course be enormously increased—a consideration of incalculable importance in the extended operations of a naval campaign.

### The Current Supplement.

Among the big things which the big State of California produces are ostriches. These birds are discussed by C. F. Holder. Mendel's laws and the origin of species are popularly discussed by Prof. Otto N. Witt. Herbert A. Humphrey writes on an internal-combustion pump and other applications of a new principle. His aim has been to produce a pump of more simplicity and strength of construction, in which the explosive force is exerted directly upon the water, and in which no rotating flywheel, solid piston, connecting rod, crank bearings, or glands of any sort are required. He describes the results of his experiments with very successful types of pumps, which have been set to work on a sufficiently large scale to demonstrate their utility and economy. Some interesting notes on Halley's comet appear in the current SUPPLEMENT, No. 1780, together with an illustration showing how the earth will be immersed in the comet's tail on the night of May 18th next. The second installment of the paper of Munroe and Hall on combustion and explosion—a primer on explosives for coal miners—is published. Dr. Ludwig Staby writes on the earth's pendulation and its effect. Census Director Durand contributes a most interesting description of the methods to be followed in the present census for counting our population by machine. The death of Delagrange calls forth an article on aeroplane accidents.

### Notes on Halley's Comet.

During December Halley's comet became bright enough to be seen with telescopes Several have reported views of it with four and three-inch telescopes Prof Philip Fox, director of Dearborn Observatory, saw it during the total eclipse of the moon on the morning of November 27th with the 3¾ inch finder of the 18-inch telescope

According to the Harvard Astronomical Bulletin No 379, Prof E. E. Barnard photographed the comet with the Bruce telescope on December 29th, and finds upon the photograph a very faint tail in position angle 69 deg with a length of 10 min The tail was very slender and straight

According to Prof E B Frost, director of Yerkes Observatory, Halley s comet will be visible to the naked eye about April 1st. It will cross the face of the sun on May 18th at which time the earth will be plunged in the comet's tail for a period of several hours The time of the comet's transit will be rather unfavorable for eastern observations, but undoubtedly it will be observed from the Lick Observatory in California and through other western telescopes. The comet will be visible to the naked eye about April 1st in the morning sky just before sunrise After it crosses the sun it will appear in the evening sky just after sunset

### Atmospheric Electricity as a Source of Power.

The futility of the schemes often promulgated for utilizing the electricity of the atmosphere, with its tension of many thousand volts, is made plain by the following considerations. According to the most reliable measurements that have been made, the strength of the current flowing from the air to the earth is about $10^{-16}$ ampere per square centimeter The maximum tension may be estimated at 100,000 volts Hence the influx of energy per square kilometer cannot permanently exceed $10^{-16} \times 10^{10} \times 10^{5}$ watt, which is equal to 1/10 watt This is equivalent to 1 kilowatt for each 10,000 square kilometers (3,861 square miles) or 1 horse-power for each 7,460 square kilometers (2,880 square miles) of the earth's surface, and amounts to about 50 horse-power for the whole of the German empire, and 50,000 horse-power for the entire surface of the globe.—Prometheus.

What is declared to be the largest and most expensive leather belt ever made for driving purposes has been recently shipped from New York. The belt is 240 feet long, 8 feet wide, three ply thick, and was constructed at a cost of $7,300. To make the belt the hides of 540 steers were required.

## Correspondence.

### THE FIRST "ALL-BIG-GUN" SHIP.

To the Editor of the SCIENTIFIC AMERICAN

In glancing over your issue of November 20th, I was struck by your correspondent's interesting article, "A Dreadnought of 1863" However, does it not seem more logical to go back a year earlier to Ericsson's "Monitor," which was without doubt the first "all big-gun" ship built. The "Roanoke" was really a combination of the "Merrimac" and the "Monitor" being like her antagonist, a rased frigate, and resembling the "Monitor" in the matter of her turrets, therefore, it appears that the "Monitor" was the original dreadnought, and the present mighty vessels of that class are but the design of the great Swedish American engineer applied to ocean-going vessels. For be it known that Ericsson never intended to employ the "Monitor" vessels for any other than coast defense duty

Brooklyn, N Y GERALD ELLIS CRONIN

### SIGHTING A RIFLE.

To the Editor of the SCIENTIFIC AMERICAN

I was interested in Mr Woodland's article, "Sighting a Rifle," in your January 22nd issue, and I would like to mention a point which I think he has overlooked, viz., the jump of the rifle This term refers to the angle through which the barrel recoils while the projectile is traversing the barrel In offhand shooting, the rifle recoils upward, and sometimes slightly sideways about a center which is probably a little forward of the butt plate The correction for this should be applied to both sights, and directly proportional to their distances from the center of recoil, but as the rear sight is very near this center, and has little vertical movement due to the jump, it is sufficient to elevate the front sight through this angle (This is done by the manufacturer, notice the high front sight of a six shooter which always has a considerable jump ) Mr Woodland's plan was evidently to make the correction on the rear sight only, and while this would keep the front sight lower, and would correct the *angle* of jump, it still introduces a constant vertical error at all ranges—an error equal to the vertical movement of the front sight While this is small, and perhaps negligible for the 0 22 calibers, it would still affect his calculations slightly The bullet would strike a little high, tending to intersect the line of sight nearer in the ascending branch and farther in the descending branch of the trajectory

Chappaqua N Y A. W BEDELL

### CURIOUS FACTS ABOUT SQUARES AND CUBES.

To the Editor of the SCIENTIFIC AMERICAN

I have discovered the following curious facts about squares and cubes. These facts, in my opinion, are interesting from a scientific point of view besides being of some practical use I shall be very glad to have you publish them if you deem them of sufficient worth.

1 To be a square a number must have for its unit's digit one of the digits 0, 1, 4, 5, 6 or 9 This, of course, is well known but I put it down as an aid in understanding the other facts.

2 To be a square a number, if its unit's digit be 0, 1, 4, 5, or 9, must have for its ten's digit 0, 2, 4, 6, or 8, i e, the ten's digit must be zero or an even number If the unit's digit be 6 the ten's digit must be 1, 3, 5, 7, or 9 i e, an odd number If the unit's digit be 5 the final digits of the number must be 025, 225, 0625, or 5625 If the units digit be 0, there must be an even number of zeros at the end of the numbers.

3 A number, to be a square, must have as remainder when "nines are cast out" of it either 0, 1, 4, or 7 Since the sum of the digits of a number gives the same remainder when divided by 9, as when the number is divided by 9, this test is easily applied by dividing the sum of the digits of the number to be tested by 9 To this test I can give an algebraic proof

4 A number, to be a cube, must have as remainder when "nines are cast out" either 0, 1, or 8 This fact also I can prove by means of algebra

I can furnish you with a device, if you desire it, by means of which, the squares of the numbers 1 to 25 being given, the squares can be written off in order *ad libitum* without any multiplications

Normal School, Peterboro G H KIRBY

### MISS PECK AND MRS. WORKMAN.

To the Editor of the SCIENTIFIC AMERICAN

After her ascent of the lower north peak of Mount Huascaran in Peru in 1908, Miss A Peck wrote in Harper's Magazine and in other periodicals and papers the following

"It may be regarded as certain that Huascaran is above 23,000 feet, hence higher than Aconcagua, 22 800 feet, and the loftiest mountain known on this hemisphere If, as seems probable, the height is 24 000 feet, I have the honor of breaking the world's record for men as well as women "

Knowing from her own statement that Miss Peck made no instrumental observations above 19,600 feet on Huascaran, and believing, furthermore, Aconcagua to be the highest mountain of the Andes, I decided to test the truth of these assertions by sending expert European engineers to make a detailed, up-to-date triangulation of the two summits of Mount Huascaran

The only previous known measurement of this mountain was made many years ago, which is said to have given a height of 22 180 feet for the south or higher summit.

Prof Schrader, who a few years ago made the most authentic measurement yet made of Aconcagua and M Henri Vallot, both well known French scientists and heads of the Société Générale d Etudes et de Travaux Topographiques of Paris undertook to assist in getting up the expedition, and gave the matter their close personal attention

M de Larminat, expert engineer who has carried out important survey work for the above society was selected as chief of the mission In July 1909 accompanied by two other competent topographers, he started for Peru

Favored by good weather conditions and assisted as to transport by the Peruvian government they executed a careful and detailed survey from the sea to Yungay and by actual measurement established the heights of four stations in the Black Cordillera, from each of which they triangulated the two peaks of Huascaran, so that Huascaran now stands as one of the most accurately measured high Andean mountains

The results are Height of north peak climbed by Miss Peck, 21,812 feet, of south peak still unclimbed, 22 187 feet These figures may vary by a few feet but not many when the calculations are finally gone over by M Vallot for verification

Mount Aconcagua nearly 22,900 feet, still remains, as I predicted and as Sir Martin Conway and other Andean explorers have always maintained, the highest peak of South America

Miss Peck's highest ascent to date therefore stands, north peak Huascaran 21 812 feet instead of 24 000 feet, as she estimated it, and she has not the "honor of breaking the world's record,' either for men or women, for my two highest ascents of respectively 22 568 and 23,300 feet debar her from that honor in the case of women while a number of men have made ascents exceeding her highest

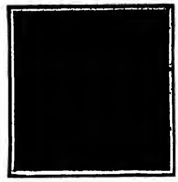
### The Argentine Exposition.

The centenary of the Argentine Republic is to be celebrated by an international agricultural exposition which is to take place this year The exposition is to be opened at Palermo (Buenos Ayres) on Friday June 3rd, 1910 and will close on Sunday July 31st 1910 The exposition will be divided into eight sections

1 Geology, Hydrology, Climatology and Geography in relation to Agriculture 2 Machinery and Implements 3 Rural Engineering 4 Vegetable products 5 Animal products 7 Means of promoting agriculture 8 Special section for seeds

Entries and application for space may be written in Spanish French English, German or Italian, and should be addressed to the Secretario de la Exposición Internacional de Agricultura de 1910 Florida 316 Buenos Aires República Argentina These entries or applications for space must be made on the printed forms which the Secretariat of the Exhibition will furnish to all persons who may apply for them at the offices of the Rural Society at the address mentioned, or to the Argentine legations and consulates abroad Entries and applications abroad can be presented at the Argentine legations and consulates general on the same dates and under the same conditions as any others.

# THE LOWE OBSERVATORY ON ECHO MOUNTAIN, CALIFORNIA, U. S. A.



BY EDGAR LUCIEN LARKIN, DIRECTOR

Do you want to imagine that you can almost near the earth in its turning? No word printed on paper can convey to the mind of a reader this impressive silence above the clouds. When Echo Mountain is within a heavy cloud the darkness is that of night. From sunset until dawn when clouds are excessively dense the jet black solitude is indeed weird. The mind is always profoundly impressed and imagination is vivid and alert. In the midst of this quietude and darkness lights are suddenly turned on by a distant hand. Night turns to day. Huge masses of metals and wires in a dynamo in Los Angeles, in rapid revolution, cause the light to flash out on the mountain top. The observatory is on a sharp peak between two immense canyons, deep and wide. The mouths of these chasms cut in herculean rocks are blacker at midnight than the imagination can conceive.

Who knows the meaning of the word *clear*? None is able to understand what clear means if living in a valley. Here on Echo Mountain the atmosphere is so clear that the stars seem near enough to touch, and the mountain air wonderfully pure. The stellar hosts glow with a brilliancy all unknown to those living anywhere near sea level. At all times, save immediately after copious rains, the dust envelope surrounding the earth is visible beneath the summit of the mountain. It covers the entire vista, even out to the sea. To us on the mountain top it seems at times as if every human would choke in this layer of dust. Above us at night, shine Sirius and Vega like huge diamonds, Arcturus and Spica likewise, and above all the giant star sun Canopus, glittering with amazing brilliancy in the distant south and flashing its rays over myriads of wave crests tossing in the Pacific Ocean. This, the brightest star in the celestial vault, cannot be seen from the latitude of New York. The magnificent constellations of Orion, Hercules and the Polar Bear are so beautiful that words are powerless to describe them. It is astonishing to behold the apparent nearness of the galaxy. Mountain perspective, the purity of the air and freedom from water vapor during two-thirds of the year combine to form an optical illusion. At times this deceptive influence approaches a night mirage, and one seems to be walking among the very stars. Here the witching hour is at sunset, a sunset of orange and flower laden plains and watery wastes beyond. Round and about the winter solstice the solar disk may be seen standing on the sea. Soon half of the mighty sphere only is visible. The last view is comparable to an arc light. Then one by one the first magnitude stars are seen flashing between distant peaks. Before the last gleam of the sun has vanished, Aldebaran, Altair, Rigel and Procyon illumine the sky.

Many gigantic sentinels, peaks, and summits lift their heads within a radius of a hundred miles of the peak. These lie to the east, to the north, and toward the sea in the west. The effect is that of an amphitheater. The south is open even down to the beach. At sunset large steamers look small indeed when compared to the face of the adjacent sun. Artists have journeyed to Echo Mountain to paint its sunset splendors, to imitate nature on canvas. But brush and pencil are as impotent as words. The view of clouds presented herewith is one of hundreds of thousands. When the first rays of the rising sun strike such cloud banks as these, prismatic colors are seen that defy description—gorgeous oranges, carnations, and heliotropes beneath. The effect is heightened by the singing of birds over the canyons. As the sun rises above the horizon the blossoming plains below, the domes and spires of Los Angeles and Pasadena, surrounded by acres of roses, with beds of delicate wistarias, and rows of flaming red poinsettias, become visible. As the clouds are dispelled, miles after miles of trained cypress, pepper, orange, lemon, apricot, almond, walnut, prune, peach, pear, and nectarine trees, together with hundreds of long lanes, drives and roads adorned on both sides with tall, graceful eucalyptus trees, are seen.

Carpet a floor with jet black velvet, and throw down upon it a myriad of diamonds in wild confusion, and perhaps you may conceive how the densely packed Milky Way appears from the observatory. Millions is a word becoming astronomically obsolete; billions of stars is an expression much more nearly true of the Milky Way. Billions of suns appear in the infinite deeps of the Galaxy. These constitute the apparent cosmic floor, the base of Nature, and of the stellar structure. In hundreds of areas, there does not seem to be place for more stars. Millions are finer than the points of fine needles, and these make a pavement of starry sand. I never really saw this sidereal base until with the telescope up here. After several days of rain, the atmosphere is swept clear of dust. Then one is really within cosmic deeps when the telescope suddenly sweeps over fathomless interstellar chasms, doors or windows through which one apparently looks into the very bottom of space. These areas are absolutely black. No sensation within the entire range of stellar research, at the hour of a mountain midnight, is so completely overpowering as the vision of an abyss in the stellar floor. Round and about these blackened wastes, there are cases where the stars are piled in heaps, raked into windrows, or strewn out into wisps, streamers, filaments, and spray. Yet of all these stellar hosts the tiniest point may be a white hot sun, and larger than our little star—the sun.

The giant nebula of Orion is a mass of starry lace, a fabric loaded with glittering points.

An astronomical telescope reverses all objects before it. The rotation of the earth is very apparent on Echo Mountain. With high powers, the stars go racing across the field of view. An incredibly startling effect is obtained when the telescope is set upon the Galaxy or Pleiades just as they rise out of some distant peak, or better, over the rim of the eastern canyon. Then millions of stars seem to be pouring into the depths of the rock-hewn abyss descending low beneath the observatory. Floods of stellar points flow downward, as seen in the reversing eyepiece.

The observatory on Mount Lowe is 70 feet in length. The peak had to be cut down to admit the foundations. The telescope is a fine Alvan Clark equatorial, with 16-inch objectives. A fine Brashear telespectroscope is here, and many other instruments.

An inclined electric-driven steel cable draws two cars from the deeps of Rubio Canyon to the summit of Echo Mountain. The length of this railway is 3,000 feet, vertical ascent 1,325 feet, and time of ascent and descent 8 minutes. The altitude of the observatory is 3,420 feet, and is 4 miles from Pasadena, 13 from Los Angeles, and 18 from the nearest shore line of the Pacific.

The railway from Los Angeles through Pasadena and Altadena lies in between orchards of orange trees. Golden fruit may be seen during five months of each year. Almond trees in bloom and orange flowers and ripened fruit are objects eliciting the admiration of all.

This observatory was founded by the dean of living aviators, Prof. Thaddeus S. C. Lowe, in 1894. Dr. Lewis Swift was astronomer in charge until August 11th, 1900.

## A Kinematograph Rifle Target.

Among the novel uses for which animated photographs have been utilized, one of the most ingenious is that recently perfected by two English inventors, Messrs. J. Paterson and J. T. Musgrave. This is its application to rifle-fire practice, the idea being to render the eye of the marksman keener, and to enable him to be more expert in the quick handling of his arm.

The "bioscope target," as it is called, is of very simple construction and operation. There are two rollers, upon which is wound a sheet of paper of any desired size, like the films of a camera, the clear space between the two rollers comprising the screen upon which the pictures are thrown. The lantern is placed behind the marksmen in such a way that their movements do not interrupt or interfere with the projection. Immediately behind this paper screen is a self recording target system, which instantaneously conveys the value of each shot to an indicator at the firing point. The value of these hits may be graduated as required. Thus the maximum points corresponding to a bull's eye are given for a fatal shot, another value for inflicting upon the objective a mortal wound, another for temporary disablement, and so on. The indicator not only communicates the individual hit, but at the completion of the round, or practice, registers and gives the total value of hits made.

The range can be varied from 15 to 25 yards as desired. The paper screen as it is destroyed by the bullet perforations is wound up on the second roller. The self recording mechanism behind the screen is so arranged that it absolutely synchronizes with the movements of the object in the picture, at which aim is taken, so that there is no possible chance of a wrong value being given for an individual shot. The indicators are placed immediately above the marksman's head at the firing position, and a fatal hit can be signified by the ringing of a bell, as with the ordinary

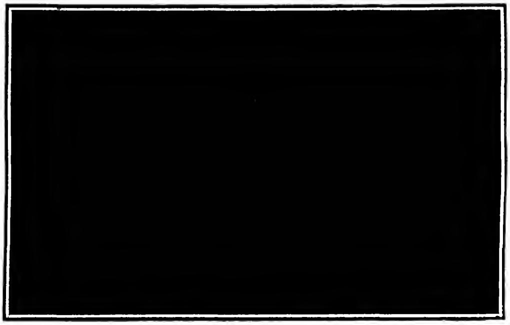
bull's eye target. The pictures, which have been specially prepared for use with this apparatus, are of such a character as to develop the celerity and certainty of the marksman's aim to the supreme degree. There is a scout scene, the enemy appearing on the picture first at a relative 100 yards range. He drops on his knee and fires point blank at the marksman a certain number of rounds, corresponding possibly to a complete charge of his rifle magazine. The marksman using the target raises his rifle immediately the kinematographic scout is seen, but does not commence firing until the scout opens fire, the appearance of a puff of smoke in the picture indicating the commencement of firing

The scout then retreats at the double to a distance corresponding to 200 yards range, when the same cycle of operations is repeated The scout then retires once more until he reaches a point corresponding to 500 yards range, and the same tactics are once more carried through It will be seen that in each phase the target becomes decreased in size, according to the range, and at the maximum range offers a very small object to the marksman Moreover, the fact that the latter has to discharge the whole of his rounds in the short period between the picture scout commencing and finishing firing at each distance, in order to score, indicates that aiming and firing must be accomplished very quickly Yet it has been found that in the course of but little practice, the marksman can pick up the range and conform with the firing conditions so expertly that about ninety per cent of fatal shots can be got in with each round at the respective ranges

The invention is also applicable to training in revolver shooting, and for this work an ingeniously suitable film has been prepared It portrays a conflict with an armed housebreaker The burglar effects his entrance through the window, under which in the room, a roll top desk is drawn at an angle In the course of his work the burglar is disturbed, presumably by someone entering the apartment. He instantly shields himself behind the desk, exposing but his head and shoulders, and cocks his revolver The burglar's disturber is represented by the marksman at the firing point, who at the psychological moment the burglar is about to fire, empties his revolver In this act the burglar presents a fair-sized target, with his protruding head and shoulders at a few yards range. The burglar having emptied his arm turns to escape through the window, but in the act of dropping from the sill, to which he clings by one hand he raises his head, and drawing his revolver once more, fires. The marksman waits until he sees the burglar's head fully exposed and just about to fire, and then shoots. In this case, owing to the greater range and the small area offered by the man's head and shoulders in profile, the area offered to the marksman's aim is somewhat small. The burglar indicator represents in silhouette the head and shoulders of the burglar in the two firing positions, and the vulnerable points of this part of the anatomy are shown on the indicator, so that the firer can instantly determine whether he has struck the target in a fatal spot, has inflicted a mortal wound, or has either missed entirely *or only inflicted a flesh wound*

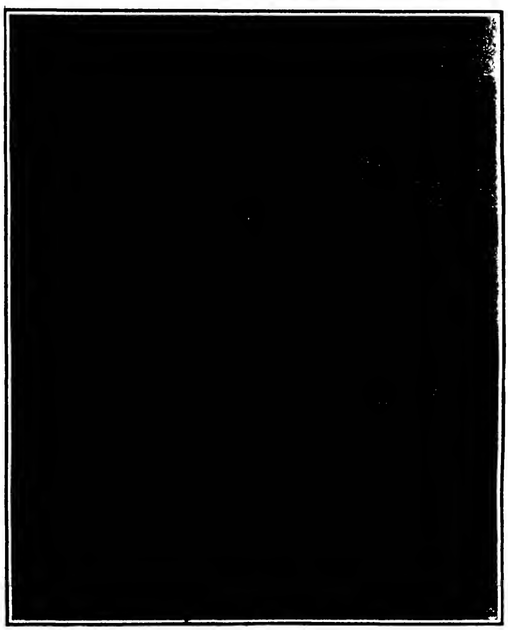
The projection is automatically controlled The lantern is electrically driven by means of a small motor, and this is operated from the firing position by means of a small switch. The same picture can be projected time after time, there being automatic devices for winding and rewinding the spool preparatory to projection Being electrically driven, a uniform projecting speed is secured, and as it is directly under the control of the marksman the apparatus is only set in action when required

The idea can be developed to an indefinite extent, and the variety of pictures that can be used for improving the fire of the marksman is endless It can be adapted for individual or company firing, and very realistic scenes can be pictorially produced. The application of the bioscope to this phase of military training has often been advocated and indeed attempted, but hitherto it has been found difficult to evolve a practical simple apparatus The British War Office has investigated and subjected the invention to searching tests, and has ascertained that marksmanship can be so rapidly improved by this means that its general introduction into the service is being contemplated.



**The cloud splendors of Echo Mountain south of the Lowe Observatory.**

The clouds in this picture are about 1,000 feet below the building Orange tree orchards are dimly seen in their shadows below



This is not a volcano in eruption but a forest fire 8 miles west of the Lowe observatory, which fire started in La Canada Valley and traveled its way to the summit, burning for several days. Colossal flames and smoke looked like a volcano in action.

**THE LOWE OBSERVATORY ON ECHO MOUNTAIN, CALIFORNIA, U. S. A.**

A new method of bonding new concrete to old was described by Mr Frank Barber, of Toronto, in a recent article in the Canadian Engineer This consists in placing bags of cracked ice on the last surfaces of concrete placed at night, thus reducing the temperature of the concrete and, consequently, retarding its time of setting, so that on the next morning the surface is still plastic and the concrete then placed will set in one mass with the old The invention of this scheme is credited to Mr O L. Hicks, when he was contractor for a reinforced concrete truss bridge in Ontario As all of the members of these trusses were of relatively small cross section the ice bags were easily placed in position, at the end of a day's work and it is stated that the method worked very successfully To what extent it could be applied to heavier work is not as yet known

Hitherto dew has been used as a beverage only in poetry, by the sun, flowers, and butterflies It has recently been robbed of all its poetic character by being used for the refreshment of English soldiers The English administration at Gibraltar, where water is very scarce, now collects dew by the following very simple method A large pit is dug in the earth and covered with dry wood or straw which, in turn, is covered either with earth or with sheet iron The straw or wood serves as a heat insulator and effectually prevents the conduction of heat from the ground to the layer of earth or the sheet iron, above Consequently this earth or iron cools after sunset much more rapidly than the ground so that its temperature soon falls below the dew point of the surrounding air Hence dew is formed upon the iron or the layer of earth in very large quantities. The water thus obtained is drained off into reservoirs and after clarification is used for drinking

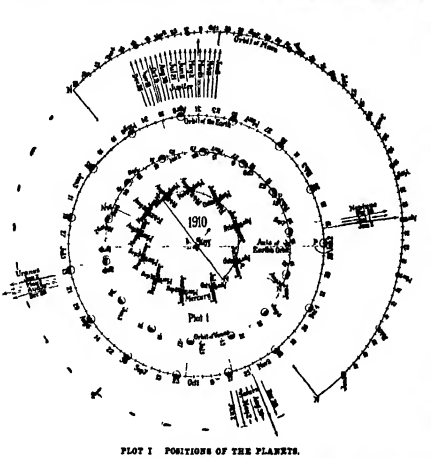
# MORNING AND EVENING STARS FOR 1910

BY PROF. FREDERIC R. HONEY. TRINITY COLLEGE

The popular expression "morning and evening stars" while signifying those planets which at different periods illuminate our skies, the observer will naturally include in his study of the heavens the fixed stars whose name indicates that they will be invariably found in the same places on the celestial sphere. Their positions in the heavens may be sooner fixed in the memory by first observing the stars of higher magnitude, whose conspicuous brightness easily distinguishes them from those of varying degrees of lesser brilliancy. In this way the heavens may be triangulated visually, and in process of time all the constellations may be easily identified. For such observations a star map is indispensable, and the positions of the stars should be located by right ascensions and declinations, which are given in the Nautical Almanac. The position of the celestial equator from which declinations are measured may be determined approximately by observing the stars which are near it on the star map, and in the same way the position of the first meridian intersecting the celestial equator at a point from which right ascensions are measured, may also be defined. Following this method seven eighths of the celestial sphere (at latitude 40 deg.) will come within the range of vision, and the heavens may become an "open book." The distances to the fixed stars are so great that (except to the astronomer) their apparent positions are not disturbed when the earth reaches the opposite point in its orbit—a distance equal to about one hundred eighty six million miles. For purposes of observation the earth may therefore be regarded as the center of the celestial sphere around which the stars appear to revolve once in a sidereal day, which is nearly four minutes shorter than an ordinary day, a difference due to the revolution of the earth around the sun once in 365¼ days. During this period the earth makes 366¼ rotations on its axis. As a consequence the stars rise nearly four minutes earlier every day, and during the year the major part of the celestial sphere comes within the range of vision at any assigned hour of the twenty four. The positions of the planets are continually changing, and in order to discover the region of the heavens in which to search for them their situation relative to the sun and earth should be determined as illustrated in Plots 1 and 2. The plots of their orbits have been printed in the SCIENTIFIC AMERICAN in the issues of the following dates: March 17th, 1906, February 9th 1907, February 15th, 1908, and March 6th 1909, and the positions of all the planets are shown for every day of each year. Together they exhibit the courses of all the planets for the five consecutive years from 1906 to 1910 inclusive. The orbits of the asteroids which are between those of Mars and Jupiter, Saturn, Uranus, and Neptune, are too small to be visible to the naked eye, the largest of over six hundred being not more than five hundred miles in diameter. Several of the orbits are very eccentric and inclined at large angles to the plane of the ecliptic.

THE SUN AND PLANETS

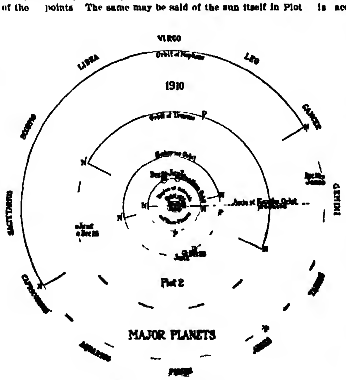
In order to bring the plots of the orbits of the planets within the limits of this page, the orbits of the terrestrial planets, which include Mercury, Venus, the earth and Mars, are drawn to as large a scale as the space permits. Since the diameter of Neptune's orbit is thirty times that of the earth, the plot of the orbits of the major planets, including Jupiter, Saturn, Uranus and Neptune, are drawn to a scale which is very much reduced. In this plot the orbits of the earth and Mars are repeated by the reduced scale, the region of the asteroids or minor planets is indicated and the plots together show the continuity of the solar system. The plane of this paper may be taken to represent that of the ecliptic or the earth's orbit, and if it be placed in a horizontal position a planet which is on one side may be described as being situated above and on the other side as below the ecliptic. In the plot of each orbit the full line represents that part which is above, and the dotted line that part which is below the ecliptic. The ascending and descending nodes $N$ and $N'$ are respectively the points where the planet passes from the space below to that above, and from the space above to that below the ecliptic, and $P$, the perihelion,



PLOT I. POSITIONS OF THE PLANETS.

is the point of the planet's nearest approach to the sun. A line joining the points $N$ and $N'$, the line of nodes, is the intersection of the plane of the planet's orbit with that of the ecliptic. To avoid confusion, only a portion of this line is represented, except in the case of Mercury's orbit.

It is obviously impossible to represent the diameter of the planets by the same scale. Even those of the giant planets Jupiter and Saturn would shrink to mere points. The same may be said of the sun itself in Plot



PLOT II.—PLANETARY ORBITS.

2, but in Plot 1 its diameter (866,400 miles) would be correctly represented by a measurement a little more than one-half of $e$, which is the linear eccentricity—the distance from the sun's center to the center of the earth's orbit.

THE EARTH

The earth's mean distance from the sun (92.9 million miles) is diminished by a little over one and one-half million miles at perihelion in January; and increased by the same distance at aphelion in July. The center of the orbit is at $e$. At a velocity of 18.5 miles per second the earth moves each day on the average nearly 1,600,000 miles, with an increase of velocity at perihelion and diminution at aphelion; making the complete revolution in 365¼ days. The position of the earth is shown at intervals of four days at Greenwich, noon, and intermediate positions and dates may be interpolated by subdivision.

MERCURY

The plane of Mercury's orbit is inclined at a greater angle (7 deg.) than that of any other of either the terrestrial or major planets. Its eccentricity is also greater than that of any of the planets. By the eccentricity is meant the distance from the center of the orbit to the sun (the linear eccentricity) divided by the semi major axis. The linear eccentricity is 7.4 million miles, and the length of the major axis is 72 million miles. Mercury's mean distance from the sun is therefore thirty-six million miles with a diminution and increase of 7.4 million miles respectively at perihelion and aphelion. At perihelion the planet moves at a velocity of thirty five miles a second, which is diminished to twenty-three miles a second at aphelion. Mercury's orbit is a marked illustration of the first two of Kepler's three laws. First: The orbit of each planet is an ellipse, with the sun in one of its foci. Second: The radius vector (i. e., the orbit radius whose length is continually changing) of each planet describes equal areas in equal times. For example, the area of the triangle with the sun as its vertex, and with a base equal to that part of the orbit included between the dates of August 30th and September 7th, is equal to the area of the triangle with the same vertex and for a base that part included between the dates October 9th and October 17th. In conformity with the second law, the length of the base of the triangle is continually diminishing from perihelion to aphelion, and increasing from aphelion to perihelion, which accounts for the rapid variation in the planet's velocity. Mercury's revolution around the sun is accomplished in very nearly eighty-eight days (87.97). This is repeated over four times during the year, and four dates are attached to each position. Owing to the great variation in the planet's velocity the positions are shown for every second day.

VENUS

The orbit of Venus is inclined to the plane of the ecliptic at an angle of 3.4 deg. The eccentricity is less than that of any other planet, and is barely visible in the plot, the distance from the sun to the center of the orbit is less than a half a million miles. As a consequence, the velocity of the planet in its orbit at a mean distance of 67.2 million miles is nearly uniform at the rate of 21.9 miles per second. The period of revolution is 224.7 days. The dates outside the orbit are those which belong to the first revolution, those within, to the second revolution, and that part of the orbit included between the positions of the planet for the first and second revolutions represents the distance traversed in seven-tenths of a day.

MARS

The orbit of Mars is inclined at an angle of 1.85 deg.; and the center $c$ is 13.2 million miles from the sun. The mean orbit velocity is fifteen miles per second, and the mean distance from the sun is 141.5 million miles. The period is 1.88 years.

THE MAJOR PLANETS.

The inclination of Jupiter's orbit is 1.3 deg., with a linear eccentricity of 22.3 million miles. The planet's orbit velocity is 8.1 miles per second at a mean distance of 483.3 million miles. The period of revolution is 11.86 years. The direction in which the planet is seen from the sun is shown at intervals of twenty days.

Saturn's orbit is inclined at an angle of 2.5 deg. The eccentricity is nearly fifty million miles; and the mean distance is 886 million miles. The planet's velo-

(Concluded on page 155.)

# CURIOSITIES OF SCIENCE AND INVENTION

### A STREET RAILWAY AUTOMOBILE.

A steam automobile street railway has recently been installed for regular passenger service between Mandeville and New Orleans, La. The cars are each fitted with a 30-horse-power steam engine and generator, making them practically automobiles on rails. The line is 16 miles long, and steam motive power has been installed in order to reduce the cost of maintenance. Two street automobile cars built as an experiment have proven so successful that more are now under construction Each car is built to seat twenty-two people, and the expense of maintaining the line under present power permits of a large saving over the ordinary electric street railway maintenance.

A STREET RAILWAY AUTOMOBILE

### GALILEO'S TELESCOPE.

Just about three hundred years ago, Galileo exhibited a telescope which he had used in studying the moon and planets. This was not the first telescope ever built, but it was however the first telescope to be used for astronomical purposes. The accompanying engraving shows how the telescope looked. This type of telescope differs from the present astronomical type in using a concave instead of a convex eyepiece, so that by a combination of but two lenses, the object glass and eyepiece, he was able to view objects right side up, whereas in the present astronomical telescopes objects are inverted The Galilean type of telescope is now used in the ordinary opera glasses With this crude instrument Galileo was able to establish the fact that the moon is a round body with its surface broken by mountains, that the Milky Way is composed of countless stars, that Venus and Mercury have phases like the moon, and that Jupiter has a number of satellites (four were discovered by Galileo) To him Saturn appeared to be a triple planet. This puzzling phenomenon was explained fifty years later by Huygens, who discovered that the planet was surrounded by a flat ring

THE FIRST ASTRONOMICAL TELESCOPE.

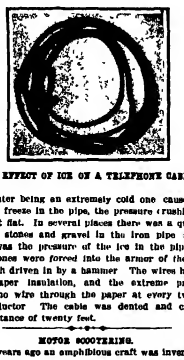
### AN EGG WITH A TAIL.

Occasionally, for one reason or another, a hen will lay a "soft-shelled" egg, but one with a tail, like that shown in the accompanying photograph, is decidedly unusual This egg was evidently the last of a clutch, and, though the hen lacked material for a shell, she had a surplus for the shell lining, or egg pod.

AN EGG WITH A TAIL.

### A FROZEN TELEPHONE CABLE

The accompanying photograph shows the effect of ice pressure on a twenty five pair lead telephone cable The cable was located in a three-inch iron pipe, and was run underground for fifty feet between the terminal pole and the manhole in the street Owing to a fault in the construction of the lateral, the pipe did not drain into the manhole, which allowed water to collect in the pipe for a distance of about twenty feet.



THE EFFECT OF ICE ON A TELEPHONE CABLE

Last winter being an extremely cold one caused this water to freeze in the pipe, the pressure crushing the cable out flat. In several places there was a quantity of small stones and gravel in the iron pipe and so strong was the pressure of the ice in the pipe that these stones were forced into the armor of the cable as though driven in by a hammer The wires had the usual paper insulation, and the extreme pressure forced the wire through the paper at every twist of the conductor The cable was dented and crushed for a distance of twenty feet.

### MOTOR SCOOTERING.

Some years ago an amphibious craft was invented at Great South Bay Long Island which could be maneuvered on ice as well as in the water It was in reality an iceboat provided with a flat-bottomed hull which would float the craft in case of encountering a blowhole or break in the ice The sport proved to be very fascinating, particularly the peculiar sensation of plunging off the ice into the water and then climbing back again The "scooter," as this craft is named, is now undergoing further development. Instead of depending upon the sail for power, Mr Nat Roe of Patchogue, L. I., has equipped his scooter with a 10-horse-power motor and a spurred wheel, which digs into the ice and drives the craft along He claims to have traveled over the ice at a rate of 90 miles per hour There is no means for propelling the boat while in the water, but the sport consists in leaping gaps in the ice by the sheer momentum of the craft He has leaped gaps of over a hundred feet in this way The motor scooter possesses an advantage over the motor sled, because it cannot sink in case of breaking through the ice, and over the sail scooter in the fact that under its own power it can be taken home over snow-covered roads when the owner grows tired of the sport

SCOOTER PROPELLED BY MOTOR-DRIVEN SPURRED WHEEL.

### LARGEST PROJECTILE IN THE WORLD

The accompanying illustration is of more than ordinary interest from the fact that it shows the largest and heaviest projectile in the world being the huge 5-foot, armor piercing shell fired from the United States government's great 16-inch rifle This giant shell and powerful gun are considered two of the most destructive and deadly engines of warfare in existence The monster 16-inch rifle the only one built so far is now at the Sandy Hook Proving Grounds, and has only been fired a few times The huge shell of steel can be hurled a distance of 20 miles or more and weighs 2 100 pounds The powder charge is nearly 500 pounds The cost of firing one shot reaches in the neighborhood of $1 000 It is not probable that this type of gun will be used but rather the 14-inch for the main coast defenses of the Panama Canal and possibly the Philippines This formidable and long range weapon though capable of firing so tremendous a projectile is too costly and fires too slowly for modern warfare

LARGEST PROJECTILE IN THE WORLD

### INTERLOCKED MOOSE ANTLERS

A curious relic of a fatal battle between two bull moose is shown in the accompanying illustration The battle was fought in the Kenai Peninsula Alaska a few years ago An Indian was attracted to the spot by the noise of the encounter, and on nearing the two antagonists he found that one had broken its neck during the struggle and lay dead on the ground while the other partly exhausted was making desperate efforts to free his horns After killing the latter moose the Indian tried in every way to separate the antlers but found this to be impossible The interlocked antlers are soon to be exhibited in the collection of heads and horns in the new Administration Building of the New York Zoological Park The larger pair of horns has a spread of 69½ inches and the other of 62 inches

RELIC OF A BATTLE BETWEEN TWO BULL MOOSE

# THE DESIGN FOR THE NEW QUEBEC BRIDGE

## COMMONPLACE IN APPEARANCE AND COSTLY TO BUILD

The collapse of the huge cantilever bridge at Quebec on August 29th 1907, was at once the greatest and most fatal catastrophe in all the history of bridge construction ancient or modern When that colossal structure broke down under its own weight and disappeared from sight in the St Lawrence River more than eighty human lives and many millions of dollars were lost in the space of a few brief minutes. Naturally the disaster caused a great loss of prestige to the engineers who were connected with the work, and discredited bridge engineering as carried on in the Western Hemisphere before the eyes of the whole world The great prominence of this bridge was due to the fact that it embodied the longest span (1,800 feet) yet attempted This was longer by 90 feet than either of the two large spans (1 710 feet) of the great Forth Bridge in Scotland, which is at present the largest bridge in existence

An investigation of the facts by a Royal Commission revealed as the cause of the collapse faulty design of the compression members It was ascertained that the management of the work was so badly organized, that the blame could not be definitely fixed to any one quarter, and in the end the Canadian government had to assume the whole money loss The work was eventually taken over by that government, and it was decided to rebuild the structure For this purpose a commission of three engineers was appointed, and it was publicly announced that the new bridge would be the finest and strongest structure of the kind ever seen

The Commission was appointed about eighteen months ago In the interim the preparation of the plans has cost about $150 000, and as the result of its eighteen months work the Commission has produced the very commonplace design, herewith illustrated, regarding which there is a general professional opinion that both structurally and æsthetically it is distinctly inferior to the Forth Bridge, which was completed nearly twenty years ago

If the bridge is built according to the proposed plans, it will not only be of inferior merit, considered from the bridge engineer's standpoint, but will also be the ugliest bridge of monumental proportions among those hitherto proposed or built. It presents the appearance of a monotonous mesh of triangles and straight lines From abutment to abutment there is not one graceful line in the whole structure, not the slightest attempt to combine the beautiful with the useful The faulty structure which collapsed had at least the redeeming feature that the outlines were structurally and æsthetically correct, and although the Forth Bridge has been made the subject of much criticism by the artist and the architect, it must be regarded as having distinct claims to beauty when compared as on the accompanying page, with the new plans for the Quebec Bridge

It would seem, however that the Board has some doubts as to the merits of its own work, for it now invites competitive plans from contractors which are to be filed by May 1st, 1910, the plans to be drawn at the contractor's own expense But if the Board has taken eighteen months' time and spent $150,000 to produce the present plans, the public will naturally ask, How can the Board expect responsible firms to furnish them with new plans in one-sixth the time and for nothing?

The lay of the land at the Quebec crossing is such as to make it almost certain that a thoroughly rigid suspension bridge could be built more cheaply, more quickly and with less risk of failure during erection On the other hand, if a bridge of the cantilever type is selected, it should be one of the first duties of the Board to see that one of the contributory causes to the weakness of the bridge that failed, namely, its extremely narrow width, is removed But, so far from doing this the authorities have not only prescribed certain limitations of width, but they have actually contracted for the new stone piers upon this restricted basis, and it is a fact that the width is such as would put a serious limit upon any bridge engineer who attempted to design either a cantilever or suspension bridge with the necessary cross-sectional width to give the proper rigidity during erection, and subsequently when express trains are crossing the structure, Those of us who knew the late Sir Benjamin Baker, the builder of the Forth Bridge, and were familiar with his cautious methods, will agree that, could he have been consulted, it is more than probable that he would have disapproved of the present design, as he would surely have condemned the old one had it been submitted to him In his Forth Bridge the width at the base of the towers is 120 feet for a span of 1,700 feet which gives a ratio of 1 to 14 This large width at the towers is necessary to insure the stability and lateral rigidity of the entire structure under wind pressure during high gales, and particularly is this provision necessary to insure safety during erection. The bridge which failed was only 67 feet wide, and this small width was a large contributing cause to the twisting of the structure during erection, which preceded its collapse This important fact does not seem to have been given sufficient consideration, for the new structure has a width of only 88 feet, or one-twentieth of the proposed length of span of 1,758 feet, as against one-fourteenth in the Forth Bridge

It may be claimed that experience with American practice in cantilever railroad bridges has shown a proportion of 1 to 20 to be sufficient, but it is a question how far their immunity from disaster during erection was due to the fortunate circumstance that no strong winds were experienced—such as frequently occur at the Forth Bridge, and may occur at Quebec —which would have twisted its trusses out of shape before they had been connected up Moreover, we believe it is a fact that there is not a large cantilever railroad bridge on this continent over which trains dare run faster than 25 miles an hour The vibrations, due to the narrow width, would become excessive, and at faster speeds would create danger of derailment. On the other hand, the advantages of great width in proportion to length are shown by the fact that the fast and heavy express trains in the north of Scotland pass continually and with absolute safety over the Forth Bridge at their full speed of from 50 to 60 miles an hour

Another element in the specifications upon which bids are invited which is puzzling engineers and contractors is that the maximum height of the towers has been limited to 290 feet above the masonry It really would seem as though the board of engineers who drew up the specifications were desirous to put weight into the new bridge merely for the sake of having it there, for it is well understood that the stresses in the top and bottom members of a truss, and therefore the amount of steel necessary to meet these stresses, increase inversely as the depth, and hence the shallower the bridge, the greater will be its weight In view of these facts, it is extraordinary that in the specifications the maximum height of the towers above the masonry should be limited to 290 feet. This height in the Forth Bridge is 330 feet, and in the Quebec Bridge which fell it was 315 feet. The

## RECENTLY PATENTED INVENTIONS.

### Of Interest to Farmers.

CATTLE-STANCHION.—M. Murphy, Grand Marais, Minn. This improvement allows the cow great freedom of movement, and no possibility of freeing herself from it, as the hook-like spur on the ring which locks the stanchion bar to the rod precludes her from so doing. At the same time the inventor provides for loosely joining the bar at both ends to the upright rod so it can swing freely about the rod without becoming detached.

### Of General Interest.

CRATE.—H. H. Cummins, Cadillac, Mich. This crate has a bottom, side walls, end walls and corner posts, each post constructed of sections arranged side by side and having abutting faces, with one of the sections of each post secured to the side walls and the other section of each post secured to the end walls, and bolts or other equivalent devices securing the sections of each post together.

SHOW WINDOW GUTTER AND FLUSHING.—H. H. Tharpe, Davenport, Iowa. The aim of this invention is to provide a gutter which may be disposed under the glass front of the window, and which is adapted to carry away all liquids resulting from condensation and otherwise. Ventilators are provided to maintain a proper temperature within the window inclosure and thus prevent condensation of moisture contained in the air.

METAL STAIRCASE.—J. F. Straiser, New York, N. Y. The improvement refers especially to the means for attaching the treads of the stairs to the staircase or stringers, the object being to provide a simple arrangement for this purpose, and in which no fastening devices passing through the treads are required. The treads are expected to be made of stone, cement or similar material.

PLUNGER LUBRICATING RING.—H. Ruth, New York, N. Y. This invention relates to a device adapted to keep the plunger of an elevator lubricated in an efficient and thorough manner. It provides means whereby an elevator plunger may be kept thoroughly lubricated by a plurality of lubricating substances, in a simple and efficient manner.

DISPLAY STAND.—E. T. Palmenberg, New York, N. Y. The object here is to provide a stand for use in stores and other places, and more especially designed for displaying belts and like articles to permit convenient selection by a customer as to style and size, the belts or other articles being securely held in place against abstraction by unauthorized persons, and at the same time to permit a salesman to readily remove any belt selected by a customer.

PIANO ACTION.—F. B. Long, Los Angeles, Cal. To render the action noiseless, the hammer rail, key board, key or other member of the action is provided on one face with a recess into which is fitted and secured a piece of cork projecting beyond the face of the member, and in the case of the hammer rail or key frame a strip of felt is secured to the rail and the frame, to overlie the projecting portion of the piece of cork.

TURPENTINE-STILL.—B. Hart, Jacksonville, Fla. In the present patent the invention consists of an improvement in turpentine stills and particularly in means for purifying the gum, etc., by straining the same to avoid the deleterious effect of wood, bark and other impurities being permitted to remain in the still.

### Hardware.

SCISSORS AND SHEARS.—A. K. Chapin, Bristol, Conn. In this invention the blades can quickly be adjusted by the employment of a spring device on the pivot, to produce the necessary tension between the blades, and thus bring the cutting edges into correct cutting or shearing position, the arrangement being such that the parts of the spring device are locked in the adjusted position, thus preventing the parts from gradually working loose and hence insuring proper working of the shears or scissors at all times.

### Household Utilities.

ADJUSTABLE WARDROBE-BED.—R. E. Carlton, Latonia, Ky. The purpose in this case is to provide a folding bed especially adapted for the use of persons suffering with phthisis, and so arranged as to permit them to breathe the outer air while the body is protected within the house. The bed may be adjusted to any height of window, and to any reasonable size of window opening.

REFRIGERATOR.—L. Doran, Port Arthur, Ontario, Canada. This refrigerator is adapted to be cooled by a cooling liquid rather than by the employment of ice, the construction being such that the liquid is distributed over an evaporating surface and air is caused to circulate over the surface to evaporate a portion of the water and thus lower its temperature.

### Machines and Mechanical Devices.

STONE-CRUSHING MACHINE.—I. L. Mitchell, Cedar Rapids, Iowa. This invention is an improvement in that class of ore and stone crushers in which a stationary jaw and movable jaw are arranged opposite each other and the latter is operated by an eccentric to impart a compound movement. It is an improvement in the means for adjusting the movable jaw toward and from the fixed jaw, as required to vary the size of the product.

CRUSHING-MACHINE.—I. L. Mitchell, Cedar Rapids, Iowa. This invention is an improvement in machines in which a movable jaw is arranged opposite a fixed jaw, the two being so placed as to form a hopper or wedge-shape receptacle for the material to be crushed. The movable jaw may be adjusted for crushing finer or coarser. Mr. Mitchell has also invented an improvement in that type of coal, ore and stone-crushing machines in which a movable jaw is pendent from and operated by an eccentric shaft, and arranged opposite a fixed jaw so that they form practically a V-shape hopper for reception of material to be crushed.

REVERSING MECHANISM.—J. R. Golter, Greensboro, N. C. In operation the washing machine is provided with a revolving washer and with gearing at the opposite ends for turning the washer, the gearing being operated alternately to turn the washer in opposite directions so that the strain of turning the washer in one direction is borne at one end of the machine, and the strain of turning it in the other direction will be borne by the opposite end of the machine.

PAPER AND PAPER HANGER.—W. P. Cronk, Burwell, Neb. One object of the invention is to provide a device in which both the paste and the paper may be held and by which the paper may be pasted by the simple act of drawing it out of the machine. Another object is to provide means for cutting off the paper at the proper length.

THREAD-HOLDER.—J. Rosenberg, New York, N. Y. The invention is an improvement in holders of the character disclosed in Letters Patent formerly granted to Mr. Rosenberg. The purpose is to simplify and generally improve the locking mechanism, which he does by providing a single bolt for each pair of oppositely disposed arms, the bolts being endwise movable in either direction to alternately engage and disengage the pins.

DETACHABLE PROPELLING MECHANISM.—J. F. Lasko, Chicago, Ill. Generally speaking, the invention consists in a screw propeller operated from the source of power through a suitable train of gears, which is adjustably attached to the stern of a boat by suitable clamps and which is provided with suitable means to ship the propeller so that it will act at various angles to steer the boat.

BARREL-FORMING MACHINE.—E. P. Everett and G. W. Norton, New York, N. Y. The intention of the invention is to provide a machine having rollers of special form, particularly adapting them for forming the bilge or curvature, and the rolls are constructed and arranged in such a way that the velocity of the faces of the rolls on the opposite sides of the web at any particular point is the same.

ANTIRATTLING DEVICE FOR BRAKE-BANDS.—J. Evans, Utica, N. Y. The invention pertains to brake mechanism such as is used on automobiles and other machines. The aim is to provide a device for preventing rattling of the brake band while the machine is running and the brake band is not in use, the device not interfering with the application of the brake whenever it is desired to do so.

ANIMAL-TRAP.—A. Marchand, Bridgeport, Wash. A main object here is to provide a platform in which the main section is hinged adjacent to the open end of the chamber and in which the trigger section is also hinged at the edge thereof toward the open end of the chamber, so that the animal in traveling into the chamber will encounter no obstacle in passing from the main section to the trigger section.

### Prime Movers and Their Accessories.

VAPORIZER HEATING DEVICE.—A. E. Osborn, New York, N. Y. This device increases ease of starting internal combustion engines, and is of especial interest, as the fuels used are tending to become heavier and harder to vaporize. The principle employed is the utilization in several ways of part of the heat of a lamp that lights the vehicles' path so that the first charges drawn into the engine will have enough heat to get a good mixture, after which the heat from the engine's operation would take care of vaporization. As the greatest difficulty in starting is at night when lamps are lit anyway, no additional trouble or expense is caused when the device is fitted to the vehicle. In fact, a saving is due to its use, for with certainty of easily starting the engine, there would be no running during stops.

GAS-ENGINE.—G. Dorffel, Fruitvale, Cal. The invention relates to gas or internal combustion engines. One object is to provide means whereby a gas engine of considerable power may be constructed to occupy a comparatively small space, and one in which the cylinders are located radially about the main or driving shaft.

DREDGING APPARATUS.—J. Ostrevold, Westport, Ore. An object of the invention is to provide an apparatus for use in removing sandbars, shoals and the like in rivers, harbors and water-ways, which require little power for its operation, and which can be adjusted for use with shoals or other obstructions of different sizes.

### Railways and Their Accessories.

TRACK-SANDING APPLIANCE.—F. G. Schwartz, Colorado City, Colo. The invention embodies an auxiliary sand feed receptacle, having discharge openings at either side and a sand supply pipe extending thereinto and terminating above the bottom of the receptacle at or near the level of the openings, whereby the sand is automatically cut off when it is piled up in the receptacle to the bottom of the pipe, leaving the discharge openings free for the delivery of the sand, and air injector nozzles extending into the receptacle and directed to blow the sand through the openings.

### Pertaining to Vehicles.

TIRE ARMOR.—C. G. Waugh, Greensboro, N. C. The armor disclosed in this patent consists of a metallic band extending around the tire in the groove in the tread. The armor band is provided with suitable spurs and is held in place by straps that extend in transverse grooves in the tire. The ends of the straps inside are bolted to the rim or otherwise suitably secured.

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## NEW BOOKS, ETC.

Kritik der Erfahrung vom Leben. By Justus Gaule, Professor of Physiology in Zurich. Leipzig: Verlag von S. Hirzel, 1906. Two volumes, bound in paper. Price, $1.50 per volume.

The author informs us that this book is the result of twenty-five years of earnest study. In that study he has had in mind the clarification of problems which seemed obscure to him in our conception of reality. He has divided his book into two parts—analysis and synthesis. In the first volume on analysis he discusses theories of the structure of living creatures as unearthed by scientific investigation. It is the purpose of synthesis to reconstruct the desired phenomena from the unities thus obtained. The book differs from most German scientific and biological works because of its simple and even graceful style. There is nothing of that involved Teutonic construction which usually makes German scientific works all but unreadable. Our limited space prevents us from giving more than the chapter headings. The first volume is divided into "general analysis and special analysis." Under "general analysis" the author sets forth why a critique of biological experience is necessary. Under special analysis he enumerates the arguments upon which a critique of biological experience must rest. In the volume on synthesis he discusses the structure of living things, symbiosis, hyphoid and zooid, manifestations of life, reproduction, vertebrate organisms, functions of centralization.

Efficiency as a Basis for Operation and Wages. By Harrington Emerson. New York: The Engineering Magazine. Pp. 171.

Mr. Emerson is a member of a new profession, viz., the directing of the great forces of manufacturing to the best advantage. He is what is called an "efficiency engineer," which in the vernacular means a doctor for a sick business. In this little book he has laid down the leading principles of this new profession and set forth very clearly the necessity of efficiency engineering to get the most out of men and machines and to cut down waste. Mr. Emerson's main argument seems to be that works management should be essentially military. It must have both line and staff. The line is the general administrative force, which reproduces itself automatically because promotion is by seniority, as in the army. The staff, on the other hand, is composed of men picked out for their peculiar qualifications regardless of age. Just as the youngest captain in the army may be an authority on aeroplanes and their military use, so the youngest man in a machine shop may be an authority on the electric drive. Mr. Emerson's methods have already found application in some of the largest manufacturing and operating institutions in the United States and have justified his criticisms of the extravagant management of railroads and large industrial works. Particularly valuable are his chapters on the realizations of standards in practice and the modern theory of cost accounting. As a piece of writing this book may be regarded as a model of forceful and terse English. The author is evidently a man of wide reading, for he is able to illustrate his point with many an apt historical allusion which adds zest to his remarks and makes his book most readable.

The Story of the Comets Simply Told for General Readers. By George F. Chambers, F.R.A.S. Oxford: The Clarendon Press, 1909. 8vo.; pp. 256.

The return of Halley's comet lends to this book a timely interest. The author has collected here all that is worth while knowing about comets in general and presented his information in a fairly popular style. This book seems to be in every way up to date, for we find in it comments upon Morehouse's comet of 1908, and upon the vagaries of that singular body. More perhaps might have been made of the radiation pressure theory of tail formation, but since the theory is mentioned a criticism on this point might seem captious. After some general remarks on comets, in which their general nature is discussed, the author passes to a physical description of comets. An excellent chapter is that on the tails of comets. In the chapter on movements of comets the author discusses the periodic and non-periodic comets, together with comet masses and the possibility of collision between the earth and a comet. Jupiter's family of comets, etc. The discovery and identification of comets constitutes the subject matter of still another chapter. Other interesting chapters are those on periodic comets of short periods, lost comets, periodic comets of long periods, Halley's comet, remarkable comets, the orbits of comets, comets in the spectroscope, the relation of comets to meteors, comets in history and poetry, and cometary statistics. The author has supplied some excellent appendices, including a catalogue of recent comets, and has given a good bibliography and ephemeris of Halley's comet from January to July, 1910.

A Manual of Forensic Chemistry. Dealing especially with Chemical Evidence, Its Preparation and Adduction, based upon a course of lectures delivered at University College, University of London. By William Jago, Fellow of the Institute of Chemistry, Fellow of Chemical Society, of Lincoln's Inn, Barrister-at-Law. London: Stevens & Haynes, Bell Yard, Temple Bar, 1909. Pp. 256.

This book is a republication of a series of lectures delivered by the author to the students of University College, London. The lectures were delivered primarily for the assistance of the chemist, and the lawyer in the preparation and adduction of chemical evidence, the lecturer's aim being to get the members of the two professions information for their mutual methods and requirements. With this object in view, the author discusses the nature of chemistry and particularly of forensic chemistry and the range of chemical evidence; the adulteration of food, under the British Food and Drugs Acts; the adulteration of drugs under the British Act; the use or non-use of new manufacturing processes; the use of preservatives and coloring matters; criminal matters; chemical evidence in civil actions and commissions.

The Wonders of Mechanical Ingenuity. By Archibald Williams. Philadelphia: J. B. Lippincott Company, 1910. 8vo.; 160 pp. Price, 75 cents.

The present volume is one of Lippincott's Wonder Series and deals in an interesting way with delicate instruments, calculating machines, workshop machinery, portable tools, oil and gas engines, motor boats, etc.

Presbrey's National Guide for Transatlantic Travelers. New York: Frank Presbrey Company, 1909. 18mo.; 128 pp. Price, 25 cents.

This little volume contains a vast amount of information relative to the sea in compact form. It should be in the hands of all ocean travelers. Its use, however, is not limited to the sea, and a copy for reference should be found in every well-regulated library. It is filled with statistical information, plans of the principal ports of call, information as to navigation, etc. No pains have been spared to make this publication an accurate and reliable compendium for the tourist.

The Wonders of the Plant World. By G. F. Scott Elliott, M.A., B.Sc., F.L.S., F.R.G.S., etc. Philadelphia: Lippincott Company, 1910. 12mo.; 155 pp. Price, 75 cents.

The titles of the chapters of this book are as follows: The Activity of Vegetables; On Savages, Doctors and Plants; A Tree's Perilous Life; On Forests; Flowers; On Underground Life; High Mountains, Arctic Snows, Scrub; On Tea, Coffee, Chocolate, and Tobacco; On Deserts; The Story of the Fields. Many of them are of entrancing interest. One of the interesting bits which we glean from it are that there are 171,781 species of plants, namely: 105,231 flowering plants, 2,819 ferns, 565 horsetails and clubmosses, 4,609 mosses, 3,041 liverworts, 5,600 lichens, 39,663 fungi and 12,178 seaweeds. These figures are for 1892, but since that time many new species have been described, so that we may estimate that nearly 200,000 species are now known to mankind. This is a sample of the many interesting features which this book has to offer.

The Story of the Submarine. By Lieut.-Col. and Brevet-Col. Cyril Field, Royal Marine Light Infantry. Philadelphia: J. B. Lippincott Company. 8vo.; 304 pp.

In this volume the author, who is known as a careful student of military history, has given an outline of the history of submarine warfare and navigation from the earliest ages to the present day. The absence of technicalities and diagrams is explained by the desire of the author to satisfy the curiosity of "the man in the street" and provide amusement for the casual reader. In this aim he has been successful. The work is clearly written, the illustrations are ample for the purpose, and, as a story, the work is possessed of a decidedly stirring interest. It is not often that an author can be his own artist, but in the present case the whole of the one hundred illustrations are from the brush and pen of

Col Field The work possesses the important quality of strict impartiality, and the degree of credit attaching to the several inventors who have assisted in bring the submarine to its present stage of perfection is assigned with excellent judgment

CANADIAN PATENT OFFICE PRACTICE Definitions for guidance in preparing and prosecuting applications and other proceedings relating to patents By W J Lynch Chief Clerk of the Canadian Patent Office Ottawa The Mortimer Press 1909 114 pp

Canada is every year becoming a very important country in which to protect inventions and the number of patent applications filed in the Canadian Patent Office is becoming so great that it [illegible] necessary for the authorities to make numerous rules on the many questions which are continually arising Mr Lynch who is the chief clerk in the Canadian Patent Office has in this book codified the Canadian Patent Act most of the sections being supplemented with paragraphs in which the practice of the Canadian Patent Office is fully explained There is no other recent book on Canadian patent practice to which a practising attorney may turn for reference and as this book not only explains the law as it has been built up from the many rulings of the Canadian Patent Office but as it also has been arranged in compact form there is little doubt that every attorney practising before the Canadian Patent Office will see the necessity of keeping one in his office for constant reference

MANORS OF VIRGINIA IN COLONIAL TIMES By Edith Tunis Sale With 67 Illustrations and 22 coats of arms Philadelphia and London J B Lippincott Company 8vo 310 pp Price $5

The stately colonial homes of Virginia which in individual cases have been the frequent subject of attention by the artist and descriptive writer are here treated collectively in a volume of undisputed charm and historical value Twenty four of the most notable manors of Virginia have been selected and the choice has been made with a wise discrimination that in a work of this character there are certain famous manor houses which must inevitably become the subject of more extended notice and while the description of each colonial home is ample particular attention has been given to such noble residences as Shirley Westover Brandon Monticello the noble pile of Berry Hill and Edgehill Accompanying each chapter is an illustration generally a front view of the mansion and a reproduction of the coat of arms of the family Other illustrations show the principal interior views and particular interest attaches to the excellent reproduction of portraits painted by the early masters of the famous owners of these famous homes The text is principally concerned with the history of the various families and the personality and fortune of their principal representatives although in each case there is a brief description of the principal architectural features of the building This work which is handsomely printed on heavy deckle edge paper is a most valuable addition to the literature on this subject

PAINTS FOR STEEL STRUCTURES By Houston Lowe New York John Wiley & Son 1910 12mo, 115 pp Cloth $1

Some forty years ago the author of this book had his attention brought daily to the consideration of the manipulation of paint its properties and the results of the various operations to which it was subjected by the questions raised by painters engineers architects builders and contractors During all this time the author has continued his observations and tests on a scale which has increased in elaboration and with careful attention to every point needing consideration This little handbook was written by a paint maker and is the direct result of study recently given to the manufacture and proper use of structural steel and the use of paint in its preservation It is published in the hope that some of the mysteries heretofore associated with the paint business may be cleared up

RHODES'S DIRECTORY OF PASSENGER STEAMERS London Published for Thomas Rhodes & Co by George Phillips & Son Ltd 1909 16mo 249 pp Price $1

The present volume is based on a publication issued some twenty three years ago entitled Holidays Afloat and after undergoing various changes results in its final appearance in this present form In 1886 the public wanted descriptions of sea trips the taste for ocean travel then just growing and Holidays Afloat met this demand The great ocean steamship companies were not slow to perceive that it would be to their interest to publish a series of booklets of a similar nature and accordingly publications of the kind were put in circulation It is not easy to sell people anything which they can get for nothing so that to meet the new conditions the scope of Holidays Afloat was extended and to the descriptions of sea trips added particulars were of sailing and fares on all the principal lines forming a sort of Bradshaw of the Ocean and also a directory of the passenger steamers mentioned in the book and the publication was renamed Rhodes's Steamship Guide But again the demand of generosity appeared on the scene and a large tourist company issued a monthly sailing list which provided more information than could possibly be obtained in an annual, therefore the scope of the book was again changed into a Directory of Passenger Steamers, giving information which would be prized in all parts of the world. The book contains a list of fleets of the principal lines of the world, then follows a directory of passenger steamers giving most valuable information relative to the builders, full dimensions, and something as to speed, accommodations, etc A new edition is in preparation which will be reviewed on publication.

THE NAVIGATOR OR MARINERS' GUIDE. A Handy Reference Work for the Use of Navigators, Yachtsmen and Students of Navigation By Capt. R. M Pugsley Jersey City New Jersey Paint Works, 1905 8vo., 202 pp.

Some idea of the importance of this book may be gained from the fact that 30,000 copies have been issued, and the second edition has been revised and added to with valuable matter not generally found in a work of this kind, and which does not exist in a manner conveniently accessible to those for whom this volume is intended, and in so doing the requirements of the practical experienced navigator and the yachtsman and student have been considered with equal care, at the same time preserving the general arrangement of the original work. Only such matter has been introduced as is known to be of real value to those interested in nautical subjects. It is filled with information which is of the greatest possible value to any ship master or officer It is well illustrated and the tables are excellent

SICILY, THE GARDEN OF THE MEDITERRANEAN By Will S Monroe Boston L. C Page & Company, 1909 12mo., 403 pp Price, $3

The present volume is the result of a tour through Sicily during the past winter and a rather extended study of the history and literature of the island The aim of the author has been to interest the general reader of travel and description and to inform prospective tourists of the Garden of the Mediterranean and to refresh the memories of those who may have already made the tour With these three classes of readers in mind, it has been necessary to cover quite a wide range of subjects of more or less popular interest The author has placed special emphasis on the distinctly human side of the subject, and while not neglecting the geography of the island and its diverse physical features, it has been, after all, the Sicilians themselves—their manners, customs, habits and institutions—that have received the lion's share of the book The illustrations are excellent and are well reproduced The paper is tinted in erra which is very pleasing to the eye This book should command a considerable sale

DER MENSCH DER VORZEIT Erster Teil Der Mensch in der Tertiärzeit und im Diluvium Von Wilhelm Bölsche Stuttgart Kosmos, Gesellschaft der Naturfreunde

In this book Mr Bolsche has presented a simply worded and therefore popular account of prehistoric man. The usual speculations on the mind of primitive man open the book whereupon the author passes to important discoveries and deductions to be drawn there from.

In the answer to Query 12,165, by an inadvertence we divided the ohms by the volts to obtain the current, instead of dividing the volts by the ohms. Of course everyone would see immediately that this was a slip and not an error of ignorance We thank our friends for their close watch of our Notes and Queries

## A NOVEL AMERICAN MONOPLANE.

(Continued from page 140)

culated through the bearings and the crankshaft by a gear-driven pump A narrow Livingston radiator is mounted in front of the motor, a short distance back of the center of the plane Two torpedo-shaped gasoline tanks connect the two sets of front and rear uprights at the center of the machine

The single surface of this monoplane consists of seven sections—a central one and three on each side Both the spars forming the front edge and the rear spar, 10 inches in advance of the rear edge, are divided on each side of the center section into three 5-foot lengths. These spars are jointed together by sheet steel sockets and are securely held in position by cables, forming a double king truss and passing over the king posts located at the junctions of the sections. The cables are attached to drill rod hooks, which are quickly adjusted Bicycle spoke nipples and eyes are made use of for tightening these cables. Heavy ribs extend from front to rear at the joints of the various sections. These ribs are trussed by an inverted rib and drill rod ties. The single surface, which is formed of Baldwin's vulcanized Japanese silk-proof material, and which is colored black according to the fancy of Mr. Pfitzner, is laced on in sections and is held to the ribs by feather bone and tacks. A section 30 inches long is left out at each end of the plane. This section is to be occupied by the sliding wing tip These wing tips or equalizers, which are 30 inches wide by 5 feet deep, have the same curvature as the main surface, and are each formed of three ribs connecting a front and rear edge, which slide in a suitable track made of steel tube rails extending the whole length of the outer section of each wing, i. e., 5 feet, and allowing the sliding tip a 30-inch travel. In their neutral position these wing tips extend 15 inches beyond the end of the wing proper When one is slid out the full distance (30 inches) beyond the end of the wing, the other is drawn in beneath the end of the opposite wing. These tips are connected by a long cable, which passes over pulleys and is wound around the control wheel, so that when the wheel is turned to the right the left wing tip is fully extended, and *vice versa*. As the area of each wing tip is 12½ square feet, when one is fully extended and the other withdrawn, there is a difference in lift at the end of the wings of about 50 pounds at 40 miles an hour, at which speed the machine lifts about 4 pounds to the square foot.

The horizontal rudder in front and the tail at the rear are mounted on two trussed rods extending about 14 feet in front of and 10 feet behind the main plane The horizontal rudder consists of a main beam about a third of the way from the front to the rear edge, upon which the ribs are mounted These ribs are connected together by a light front edge of wood and at the rear by a wire cable The rudder is balanced At its right end is a double vertical lever, which is connected by wires to a similar lever on the transverse shaft at the base of the control column The latter lever can be seen in the three-quarter front view of the machine A forward and backward movement of the control wheel depresses or raises the horizontal rudder The vertical rudder is connected to the control wheel in such a way that when the wheel is rotated about its vertical axis the rudder is set to turn the monoplane The motion is the same as that used in steering a bicycle The vertical shaft of the control wheel is mounted in a 4-inch bearing in the supporting bracket, the transverse steering lever being just below this bearing Cables connect the ends of this lever to a similar one on the vertical rudder In order that the length of these cables may remain the same during the fore-and-aft movement of the control wheel, the bracket at the base of the control column is arched so that the ends of the steering lever just mentioned are in the center line of motion The cable that operates the wing tips, and which is wound around the circumference of the steering wheel in a groove, is led by means of pulleys through the hollow shaft of the control column It leaves the pulleys in the center line of motion, so that its tension is in no way affected by the other movements of the control wheel. The throttle lever for the carbureter is placed on the side of the control column; a cable passes through this hollow shaft and over pulleys to the carbureter A switch button for short-circuiting the magneto is also mounted on one of the spokes of the control wheel. This whole controlling mechanism is extremely simple and doubtless will be widely used in the future, as we understand it is the inventor's intention to give it to the public and not to patent it.

All the woodwork used in the construction of this monoplane is of spruce. The spars and struts are solid and have their front and rear edges tapered, while the ribs are laminated With the exception of the motor, radiator, and steel cables, the whole machine is finished black and

(Concluded on page 151.)

# INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending February 1, 1910,

AND EACH BEARING THAT DATE

# Important Books

## Modern American Lathe Practice

By OSCAR E. PERRIGO, M.E.

Price $2.50

A COMPLETE book of 400 pages on The Modern American Lathe. Its development from the earliest times up to the present day its modern form as constructed by up-to-date builders its general and special classes of work the quantity of its output, and its marvelous accuracy.

## Modern Steam Engineering in Theory and Practice

By GARDNER D HISCOX M.E.

Price $3 00

THIS is a complete and practical work of 487 pages, dealing with the care and management of Boilers, Engines Pumps, Superheated Steam, Refrigerating Machinery Dynamos, Motors, Elevators, Air-Compressors, and all other branches with which the modern Engineer must be familiar.

Nearly Two Hundred Questions with their Answers on Steam and Electrical Engineering likely to be asked by the Examining Board are included. These if studied by you will help you to procure a license. It is fully illustrated with detail engravings, not to be found elsewhere.

## Punches, Dies and Tools for Manufacturing in Presses

By JOSEPH V WOODWORTH

Price $4 00

A PRACTICAL work of 500 pages fully illustrated by nearly 700 engravings, being an encyclopedia of Die Making, Punch Making, Die Sinking, Sheet Metal Working and Making of Special Tools, Subpresses, Devices and Mechanical Combinations for Punching Cutting, Bending, Forming Piercing Drawing, Compressing and Assembling Sheet Metal Parts, and also Articles of other Materials in Machine Tools. Two Hundred and Ten Processes are clearly described and fully illustrated.

## A Complete Electrical Library

By Prof. T O'CONOR SLOANE

An inexpensive library of the best books on Electricity. Put up in a neat folding box. For the student, the amateur the workshop, the electrical engineer schools and colleges comprising five books, as follows

| | | |
|---|---|---|
| Arithmetic of Electricity 138 pages | | $1.00 |
| Electric Toy Making, 140 pages | | 1.00 |
| How to Become a Successful Electrician 189 pages | | 1.00 |
| Standard Electrical Dictionary 682 pages | | 3.00 |
| Electricity Simplified 158 pages. | | 1.00 |

*Five volumes, 1,300 pages and over 450 illustrations*

*A valuable and indispensable addition to every library.*

OUR GREAT SPECIAL OFFER — We will send prepaid the above five volumes handsomely bound in blue cloth with silver lettering and inclosed in a neat folding box, at the Special Reduced Price of $5.00 for the complete set. The regular price of the five volumes is $7.00.

## The New Agriculture

By T BYARD COLLINS

12mo, 374 Pages, 100 Illustrations Cloth. Price, $2 00

This valuable work sets forth the changes which have taken place in American agricultural methods which are transforming farm life formerly so hard into the most independent peaceful and agreeable existence. Farm life to-day offers more inducements than at any previous period in the world's history and it is calling millions from the desk. The present work is one of the most practical treatises on the subject which has ever been issued.

The latest and best book on the subject. Contents I. The New Call to the Farm —II The New Soil —Irrigation.—III The New Fertilization. IV The New Transportation.—V New Interests - VI New Creations.—VII. New Varieties. VIII New Practice —IX New Machinery —X. The New Inspiration

## HOME MECHANICS FOR AMATEURS

By GEORGE M. HOPKINS.

Author of "Experimental Science"

12mo. 370 Pages. 320 Illustrations

Price, $1 50 Postpaid

The book deals with wood working household ornaments, metal working lathe work metal spinning silver working making model engines, boilers and water motors; making telescopes, microscopes, and meteorological instruments, electrical chimes cabinets bells night lights, dynamos and motors, electric light and an electrical furnace. It is a thoroughly practical book by the most noted amateur experimenter in America.

## Electrician's Handy Book

By PROF T O'CONOR SLOANE, A.M., E.M., Ph.D.

Handsomely Bound in Red Leather, with Titles and Edges in Gold. Pocket Book Style. Price $3 50

A THOROUGHLY practical reference book of 768 pages, covering the entire field of electricity. Contains no useless theory. Everything in it is to the point and can be easily understood by the student, the practical worker and the everyday working electrician. The advanced electrical engineer will also receive great benefit from its perusal and study.

*A special circular describing these books sent on request.*

*Any of these books sent prepaid on receipt of price.*

Publishers, 361 Broadway, New York

(Concluded from page 150)

makes a very striking appearance. Mr Pfitzner has already made a number of short flights in which he was able to get off the snow-covered ground within a distance of about 100 feet. The machine is very speedy and so far has shown excellent stability. On one occasion it whirled completely around when the vertical rudder was turned too sharply and yet in doing this it kept a level keel and was not damaged. The running gear has been broken and will have to be made somewhat stronger, but otherwise the machine has shown itself to be very strongly and well constructed. The novel sliding wing tips used on this machine are quite different from the system of warping the planes used by the Wright brothers, and from the first trial flights at least they appear to be fairly effective. Not until more extended flights have been made however can their true value be determined.

### SMOKELESS POWDER

(Continued from page 151)

dry in some ways—the cotton being digested in centrifugal wringers of a sort akin to those in which clothes are washed. The atmosphere is intensely acrid and the stranger coughs in the biting air, to which the throats of the operatives seem to be indifferent. When the cotton has soaked sufficiently, it shows signs of heating by emitting a dense brownish smoke. It is then tumbled into vats of running water, and there "drowned" before being wrung out in another mechanical wringer. The cotton, before innocent has become an explosive in fact, is guncotton or pyro-cellulose. Its subsequent stability and value as a propellant now depend upon the thoroughness with which all trace of the transforming acid are extracted from the "pyro," as it is commonly called.

To this end, the "pyro" is next put into open tubs loaded upon a flat car, and carried to steaming tanks where for two days it is boiled and boiled to extract the major part of the clinging acid. We know we are dealing now with an explosive by the sharp reports that come from under the car wheels as they pass anon over small bits of nitrated cotton. Next the stewed cotton is taken to the pulping house, where it is pulped and poached like the materials used in paper making. The water is changed often, and after twenty or thirty hours working, the "pyro" is quite freed of the last trace of acid. These various operations do not undo the nitrating. The chemical metamorphosis accomplished in the cotton by the acid is permanent, and the boiling and washings serve only to remove spent and unabsorbed acid. The slimy pulp is now put through a "wet machine" coming from the rollers in flakes containing about 40 per cent of moisture. Thence it goes to the dehydrating house, where all but a small percentage of the moisture is extracted by successive applications of pressure and, finally, by the use of alcohol which drives the dampness before it leaving just enough of the spirits behind to form the needful solvent when ether is added. The ether is poured in and the stuff is ground and mixed in a mechanical kneader. After half an hour's working the material resembles damp cracker crumbs. Chemically the pyro is now solvent and has undergone another change, requiring only the proper amount of pressure to produce homogeneity. The "colloid" for such it is is then pressed into cakes weighing fifty pounds, which suggest soft rubber and are dully resonant. The stuff is no longer white but looks like syrupy maple sugar. The amber-colored cakes are then subjected to a heavy pressure and the plastic stuff forced through steel collanders whence it issues in cords like solid macaroni. Again, for the sake of more perfect union these cords are pressed into a single compact cake, and then the plastic mass is

(Continued from page 151.)

placed within the cylinder of the powder press.

Under an impulse of from 4,000 to 6,000 pounds pressure to the square inch, varying with the size of grain, the powder issues through dies in the form of an endless snake of pale yellow, perforated from end to end with a concentric group of circular passages. As the cord comes from the press it is cut into grains of uniform length; the size of these units and the number of perforations depending upon the caliber of the gun. The purpose of the small lengthwise passages is to insure a compensating burning surface, which increases directly as the external grain surface diminishes under the attack of the flame. This gives the powder its *progressive* burning quality, so needful in securing the desired ballistic results without undue stress upon the weapon.

The actual fashioning of the powder is now complete; but there are still things to be done before it is fit for issue to the service. As it was with the nitric acid, so too is it with the ether-alcohol solvent, the stability of the powder depending upon the degree to which this volatile is extracted. Some of this solvent is removed by distillation, and thousands of dollars worth of it are recovered annually and used again. The final stage of dryness is reached by storage in drying houses, the period varying from six weeks to six months according to the size of the grain. Then, after being tested by actual firing, and mixed with grains of other groups to secure a desired average, the powder is put up in air-tight tanks ready for issue. The object of careful sealing is to arrest the escape of the remaining solvent, which acts as a deterrent and prevents the explosive from becoming too quick in its burning, thus serving to check the development of sudden and dangerously high pressures in the gun.

Smokeless powder can be dampened, and, provided it does not mildew, is as good as ever if properly dried again. After eight or ten years the powder becomes unstable and even crumbles, but it can be sent back to the factory, be reworked, and turned out once more a good explosive at an outlay of only one-fourth of its original cost. This is proof of the indestructible nature of its base—pure cellulose—which however defies the cunning of the chemist and holds secret the ways in which sunshine, oil, and atmosphere work mysterious differences in the minute cells of each delicate filament. The cotton from Georgia does not make the same powder as that from Alabama, and the blooms of Tennessee give us the best propellant. The problem for the manufacturer is to combine these various growths, so that he can make the nearest approach to a perfect and uniform powder. Each lot of powder has its own characteristics within limits, and a sample of each lot is kept under continual scrutiny in a surveillance magazine so long as any of these lots are in service. Daily, these telltale samples are examined. If changes of a vital nature are detected, information is at once dispatched to every ship upon which the affected powder is carried.

Though smokeless powder has proved a boon, still it has one serious fault which has not been effectually overcome; its explosive temperature is quite 4,500 deg. F., and this is nearly twice the melting point of steel—the material from which we make our guns. The development of this intense heat is merely momentary, yet it damages seriously the bore of the gun if the hot gases escape past and ahead of the moving shell, because they act like the flames of a powerful blowpipe and sear away the rifling surfaces of the weapon. Here is a problem for the chemist. Smokeless powder is not as easily ignited as ordinary gunpowder, neither can it be detonated by a blow, and a small quantity of the old black propellant is added to each charge to facilitate

**MORNING AND EVENING STARS FOR 1910.**

(Continued from page 148)

ity in its orbit is 6 miles a second, and the period is 29 46 years Saturn's position is indicated at intervals of sixty days.

The plane of the orbit of Uranus is inclined at an angle of 0 77 deg to the ecliptic, which is less than that of any of the other planets The mean velocity is 4 2 miles per second at a mean distance of 1,781 9 million miles The center of the orbit is 82 6 million miles from the sun The planet completes its revolution in 84 02 years, and its position is shown at intervals of 120 days Neptune's orbit is inclined at an angle of 1 8 deg Notwithstanding the planet's great distance the linear eccentricity is only twenty five million miles The orbit velocity is 3 4 miles per second, and the mean distance is 2,791 6 million miles The revolution is accomplished in 164 78 years, and the planet's position is shown at intervals of 180 days

Neptune's distance from the sun is a very little over thirty times that of the earth $\left(\frac{2791\ 6}{92\ 9} = 30\ 055\right)$ The square root of the cube of this number gives the period, which is 164 78 years This illustrates Kepler's third law, viz The squares of the periods of the planets are proportional to the cubes of their mean distances from the sun By similar computations the relations between the periods and mean distances of all the planets may be shown to be those which are here given

HOW TO DETERMINE THE MORNING AND EVENING STARS

A planet whose orbit is within the earth's orbit is morning star between inferior and superior conjunctions and evening star between superior and inferior conjunctions Prior to conjunction a planet outside the earth's orbit is evening star, after conjunction it is morning star It should be noted however that when a planet is near conjunction, it is not far enough away from the sun for observation The longest arrows indicate the directions in which the major planets are seen at opposition, the shortest arrows the directions in which they would be seen at conjunction if the sun were out of the way At the date of opposition a planet is visible before and after midnight, and is therefore both morning and evening star

If the page be turned about one-quarter of the way around so that the earth in Plot I on January 8th (the date of the opposition of Neptune) is between the reader and the sun the positions of all the terrestrial planets on this day may be seen without turning the head The earth rotates in the direction of the arrow At sunrise an observer emerges from the shadow area at sunset he enters it All planets which in the plot are on the right rise before the sun and are morning stars, those on the left set after the sun, and are evening stars On January 8th Neptune is above the horizon before and after midnight, and is both morning and evening star Conjunction of Uranus with the sun occurs on the 11th Previous to this date Uranus is evening star, and subsequently morning star On January 7th Saturn is at quadrature, and is evening star On January 4th Jupiter is at quadrature, and is morning star On January 17th Mars is at quadrature, and is evening star On January 25th Mercury reaches inferior conjunction Before conjunction the planet is evening star and after conjunction it is morning star During the month of January Venus is evening star The planet is at inferior conjunction on February 12th, and after this date is morning star

The table gives the dates of conjunc-

## THE DESIGN FOR THE NEW QUEBEC BRIDGE.

(Concluded from page 148)

low height of 290 feet necessarily increases the weight of a cantilever, and if used for the towers of a suspension bridge would result in a flat catenary, requiring unusually heavy and expensive cables and anchorages. The great height of the towers and trusses in the Forth Bridge has an important bearing upon its rigidity under fast trains.

The effect of low height and narrow width in raising the weights is shown in the fact that the amount of steel to be put into the Quebec Bridge in a length of 2,800 feet is estimated at over 66,000 tons. The total amount of steel in the Forth Bridge in a length of 5,300 feet is 53,000 tons. In other words, the narrow Quebec structure would require the enormous average amount of 24 tons of steel (about half of which moreover is nickel steel) per lineal foot, whereas the wide and rigid Forth Bridge required an average of only 10 tons of carbon steel per lineal foot. It is true that the train loads assumed for the Quebec Bridge are about three times as heavy, but it is well understood that the weight of steel in any bridge of great span does not increase in anything like the same proportion as the live load.

## NEW OVERHEAD ELECTRICAL CONSTRUCTION ON THE NEW HAVEN RAILROAD.

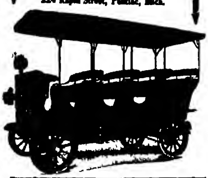
(Continued from page 140)

building, through the Westinghouse Company, an experimental freight locomotive, preparatory to operating its whole service, freight and passenger, from New York to New Haven, a distance of between seventy and eighty miles, entirely by electric power.

At the time of its construction the present twenty-three miles of electrified line between Woodlawn and Glendale, two miles beyond Stamford, was one of the most courageous and costly experimental works ever undertaken in the broad field of electricity. The story of the unparalleled difficulties with which the company had to contend in developing the system to its present perfection, and at the same time keeping in operation one of the busiest four-track railroads in the world, has been told from time to time and in considerable detail in these columns. To-day this electric zone is running with the regularity of a watch, as may be judged from the fact that the delays through breakdown of the electrical locomotives are shown by the statistics of operation to be 100 per cent less than were the delays under operation by steam locomotives.

The experience gained during the past two or three years has revealed to the engineers some features in which the electric plant is capable of improvement. Particularly is this true of the overhead

(Concluded on page 155.)



(Concluded from page 154)

work, which in the existing line is of a massive and decidedly costly type of construction In addition to its expensive nature, the present overhead line was found to have unnecessary rigidity, and it was decided that before extending the work to New Haven it would be wise to build a mile of experimental line, embodying the improvements suggested by past experience We present two photographs and a diagram which clearly illustrate the character of the new work In the old construction the line is carried upon massive steel bridges, spaced 300 feet apart, each bridge consisting of a pair of columns supporting a latticed truss which spans the four tracks Each trolley wire is hung from a pair of steel 'messenger' cables by means of a series of triangles, the messengers being hung in a true catenary and fastened to insulators attached to the top of the latticed trusses The trolley wire, which is maintained in a horizontal position passes below the supporting trusses The whole of this system—messenger cables, triangles, and trolley wires—is charged with current at the high potential of 11 000 volts

In the new system a successful attempt was made not only to lighten the construction, but also to provide one whose appearance would be lighter and more graceful Furthermore, the cables and wiring have been so arranged that the main carrying cables and the main pipe hangers are not charged, and the only live portion of the work is the catenary trolley, and contact wires

By reference to the engravings it will be seen that the place of the massive bridges is taken by a pair of relatively slender tapering, columns, which are curved inwardly until they terminate above the centers of the outside tracks To hold the columns in a vertical position and prevent their sagging under the load of the cables a length of steel pipe trussed with wire, is introduced between the opposite incurving ends of the columns The duty of carrying the wiring falls upon two 1¼ inch steel wire cables which are secured at the ends of the latticed columns, and extend continuously throughout the whole line Depending from these cables at intervals of 100 feet are a series of main pipe hangers each of which consists of a horizontal 3 inch pipe which is hung from the cables above by two pairs of supports formed of 1½ inch pipe All of this construction thus far described, columns, main cables and main pipe hangers, is at all times dead none of the current being allowed at any time to pass through it—a feature of the greatest importance when it comes to the question of making quick repairs to the line, or of adjusting the set of the cables Attached below the transverse horizontal members of the pipe hanger are four porcelain insulators, which are adjusted so as to lie vertically above the four tracks, and this feature of adjustment is one of the great improvements of the new over the old line Upon the insulators are strung the four steel track messenger catenaries, below which, carried on short vertical pipe hangers of graduated lengths, is the copper trolley wire An inch or two below the trolley wire and supported therefrom by steel clips, is the steel contact wire, against the under side of which the collector shoes of the locomotives bear with an upward pressure of about 25 pounds The method of attaching the contact wire to the trolley wire at points intermediate with the points at which the trolley wire is itself suspended, provides a system of equalization which gives to the system an even flexibility throughout its whole length, and insures a continuous contact and a consequent freedom from sparking

The management of the electrical zone of the New Haven Railroad Company and its engineers are to be congratulated in having made such a marked improvement, both from the constructive and æsthetic standpoints, over the existing line between Stamford and New York

## SECRETARY MEYER'S PLAN FOR THE REORGANIZATION OF THE NAVY

THAT one of the first acts of Mr. Meyer on assuming the extremely difficult and responsible position of Secretary of the Navy, would be to make a thorough investigation of conditions with a view to placing that very complicated department upon a more practicable working basis, was inevitable, as everyone must have foreseen who is familiar with the excellent work of reorganization which he achieved while holding the position of Postmaster General.

The changes introduced by Mr. Meyer are necessarily supplemental to the work of his predecessor Mr. Newberry, who had formulated and put into effect a system of consolidation which, in the brief period of its operation, had shown excellent results. Mr. Meyer has assured us that the changes which he has instituted in the Newberry plan have been made not for the purpose of reversing but rather of amplifying the work of consolidation inaugurated by his predecessor. The essential changes involved in Mr. Meyer's plan are summarized under the following heads:

(1) The provision of four responsible advisers (of the Secretary) on subjects within the groups into which duties of the Department logically fall.

(2) The grouping of the Bureaus into two divisions of material and personnel according to the nature of their duties.

(3) The establishment of a Division of Operations of the Fleet.

(4) The establishment of a comprehensive inspection system of a permanent organization whose officers shall be periodically changed, who will come mainly from the active fleet and be conversant with the latest ships and the modern methods of drill and organization.

(5) The establishment of a modern and efficient cost keeping system in the Navy Department and at navy yards.

(6) The separation of navy yard work into the two natural divisions of hull and machinery.

(7) He intends to require that commandants and captains of yards for navy yards shall be selected for their knowledge and experience and that their tenure of office shall be long enough to insure continuous administrative policy.

The SCIENTIFIC AMERICAN has before it the printed record of the hearing of the Secretary and various Bureau chiefs before the House Naval Committee appointed to consider the proposed reorganization, and, after giving the same a most careful reading, we have come to the conclusion that, with one very serious exception, the measures proposed by Secretary Meyer are well adapted to promote that consolidation which Mr. Newberry began and which the present Secretary is endeavoring to place upon a lasting workable basis. The appointment of four aides, independent of the Bureaus, whose duties will be to inform and advise the Secretary on matters coming under the four general heads is an excellent arrangement the need for which had been keenly felt by previous secretaries. The Aides for Operations of the Fleet, for Personnel and for Inspections are to be line officers. The question as to whether the Aide for Material should be chosen from the line or staff is left open. We are decidedly of the opinion that in seeking for advice on the question of material, that is ships, engines, navy yards, etc., the Secretary should have as his aide the Chief or some high ranking Naval Constructor, who by training and experience is best qualified to advise upon these subjects. A proportion of three line officers to one staff officer among the aides would give a fair representation of both branches of the service, and would put the Secretary adequately in touch with the whole range of active work in his Department.

The feature of Secretary Meyer's plan which we consider to be open to very grave question is the proposal to separate the navy yard work into two divisions of hull and machinery, with a separate and independent manager for each, for the change involves the defeat of one important object of the Newberry plan as affecting the navy yards, namely, the securing of efficiency, and the avoidance of confusion and delay, by placing the whole of the work affecting the construction of the ship in charge of the officers of a single corps with a member of that corps as general works manager of the yard. Mr. Meyer recognizes that a navy yard is a military establishment and must be under military government, but this condition was met under the Newberry plan by placing at the head of the yard a commandant who is always a line officer of high rank. Under him came the manager, a naval constructor whose executive powers were recognized as covering not the military, but the industrial side of the work. In view of this distinction, we fail to see how the management of the yard as to its non-military and purely industrial features by a staff officer of the naval construction corps is, in any possible sense, a violation of that law of Congress, according to which a staff officer cannot exercise military command over any other than members of his own corps. Under the former or Newberry plan, line (sea-going) officers of the Engineering Corps, who were temporarily assigned to the steam engineering department at the navy yard were subject to the naval constructor manager, purely in the industrial and not in the military sense.

If it is advisable for economy and efficiency, and the consensus of evidence is overwhelming on this point, that the navy yards should be under a single industrial management and that this management should rest in the naval construction corps, and if under such an arrangement any legal question is involved as to the right of the constructor-manager to exercise non-military authority over engineer officers of the line who may be temporarily assigned to duty at the yard, then the sooner the law is modified the better for the interests of the navy, and of the American people as a whole.

If it be asked why both hull and machinery should be placed under the control of a single head, and that head the naval constructor, we reply that the hull and the machinery are merely subdivisions of one organic whole, and that the two are an greatly interdependent as to make it necessary that their design, construction and subsequent repair be under the management of a single corps, who are qualified for the work by training, knowledge and practical experience. Now, we venture the statement, without any fear of successful contradiction, that the one body of men who combine the necessary knowledge of naval architecture and steam and electrical engineering to qualify them for the oversight of the construction and repair both of the hull and the machinery is the corps of naval constructors. Unfortunately, much of the evidence which has been given before the committee has been directed to proving that the naval constructor is ignorant of steam and electrical engineering and therefore not qualified to take charge of the shops devoted to these branches at the navy yards. That nothing is further from the truth is shown by the following consideration of their training and experience.

In the first place the naval constructors are the pick of the Naval Academy graduates. They are selected from the highest numbers in their class, and, as a rule, have been taken from the first two or three. In making the selection, in addition to their academic standing careful consideration is made of their general aptitude for the service as shown during their three or four years at sea, of their general officer-like qualities, and of their aptitude for the handling of men, and for general administration. The principle of selection is the same as is followed in the case of that other highly specialized and most efficient body of professional men, the corps of engineers of the army. After their education as line officers at sea the constructors are given at the famous Massachusetts Institute of Technology a post-graduate course in naval construction, which is the most thorough of any in the world.

Furthermore (and we cannot too strongly insist that the impression that the naval constructor is not a qualified steam engineer is absolutely erroneous) the course at the Massachusetts Institute of Technology involves also thorough instruction in steam and electrical engineering during which the prospective constructors are given a course of practical training in the machine shops and laboratories of the institution.

The life work of the naval constructor will be done on shore and mainly at the various navy yards, and by virtue of his long residence at these yards, or as inspector at the various private shipbuilding yards, he gathers an ever-increasing and immensely valuable knowledge of the operation of these great industrial plants. Future promotion and distinction for him lie along these lines. There is every incentive for him to become thoroughly proficient.

With the line officer, however, into whose hands Mr. Meyer's plan would commit the construction of all electrical and steam machinery, and the management of the large and elaborate plants at the navy yards where this work is done, the case is entirely different. After his four years' course at Annapolis, the prospective naval engineer goes to sea with the expectation of spending practically all of his time afloat, and, naturally, his sympathies, interests, and above all his ambitions, will be connected with sea duty. An assignment for service ashore is merely a break in the routine of his chosen life work. If the line officer be an engineer officer, he will enlarge at sea his knowledge of the care and operation of a ship's machinery, but since by far the greater part of his time is spent afloat, his opportunities for becoming acquainted with the complicated and difficult work of managing such large industrial concerns as the steam machinery shops of the navy yards are, in the nature of things, very limited. His work is to run not to build, the engines, just as it is the work of the captain of the ship to run and not to build the hull.

Even when the line officer is ashore, his interests and future aims are still upon the sea, and, as a rule, he is only too glad when the next assignment for sea duty comes. Proof of this is found in the fact that during the past six years there have been at our seven leading naval yards, no less than 29 commandants and 41 captains of the yard. Evidently, the sea-going officer cannot too quickly get back to his natural sphere of service.

If there were available at the present time a corps of engineering officers who, like the naval constructors, had been specially trained for shore duty in the management of the machinery shops, etc., at the navy yards, we would have more hope of the success of this particular part of Mr. Meyer's plan, but outside of a few of the older engineers, trained under the system which obtained before amalgamation, no such body of men is available. Furthermore, it is our conviction that were such a body existent it would still make for economy and efficiency, if both hull and machinery were placed under the single management of a naval constructor.

That part of the Newberry plan which affected the navy yards was giving very promising results at the time Mr. Meyer took office. We have little doubt that his determination to separate hull and machinery was governed largely by certain alleged instances of incapacity of the naval constructors in their management of the machine shops which were supplied to the Secretary, most of them over the signature of the Engineer in Chief. The testimony before the House Naval Committee now before us, however, shows that a subsequent examination of these reported cases has elicited from the commandants of the various yards (all of them line officers) a complete disproval of the charges as made—a very gratifying vindication of the work of the naval constructors in this particular regard. We cannot but feel that with this later evidence before him, the Secretary will be disposed to reconsider that part of his otherwise excellent reforms, which proposes to separate hull and machinery and that he will allow the Newberry plan of a single management sufficient time to further demonstrate the economy and all round efficiency of which it gave in the few months of its operation such great promise.

## ELECTROLYTIC REMOVAL OF GREASE.

AN electrolytic method of removing grease from objects has been introduced in Germany. Grease can be rapidly removed from metallic objects by employing it as a cathode in a hot solution of potash or soda lye. It was supposed that the alkali metals set free at the cathode transformed the fatty matter into soap, but Barth has now shown that substances which cannot be saponified, such as machine oil, paraffine oil and paraffine, are removed very quickly by the current, and he explains this fact by mechanical action caused by bubbles of hydrogen which come off at the cathode. This action is produced only when the fatty matter is liquid. If the temperature of the bath is too low so that the grease is consistent, the removal is very slow and is incomplete. He operates with a moderately concentrated solution of carbonate of potash heated between 85 and 100 deg. C. As the anode he uses sheet iron or carbon pieces. When a piece of sheet iron covered with oil or paraffine is dipped into this bath it remains covered with oil ten minutes after immersion when the current does not flow, but upon sending the current all traces of oil disappear in a few minutes.

To permit two steamers to pass from the Wisconsin River to the Mississippi River, near Prairie du Chien, Wis., a railway bridge on the Chicago, Burlington, and Quincy Railway was raised by breakdown cranes a few weeks ago. There is no navigation on the Wisconsin River, but the two steamers were sent down to enter service on another route. The railway crosses the river near its mouth, and a 65-foot span was raised about 6 feet to clear the steamers' funnels.

## ENGINEERING.

**George W. Melville,** Engineer in Chief of the United States Navy, states that there is every reason to believe that two ships of the navy will be fitted with the turbine reduction gear which we illustrated on the front page of our last issue It is proposed to re-engine the "Baltimore" with turbines of 12,000 horse-power and equip one of the new colliers with turbines of 6,000 horse-power, both employing this reduction gear

**The number** of persons killed in train accidents during the months of July, August, and September, 1909, as shown in reports made by the railroad companies to the Interstate Commerce Commission, was 193, and of injured, 3,752 Accidents of other kinds including those sustained by employees while at work and by passengers in getting on or off the cars, etc, bring the total number of casualties up to 20 093 (852 killed and 19,241 injured)

**The Shoshone** dam in Wyoming, which forms the leading feature of one of the projects of the Reclamation Service, has recently been completed It is built of concrete, and measures 328 4 feet from foundation to the crest It is 175 feet long at the top and 85 feet long at the bottom, where its thickness is 108 feet The reservoir back of the dam, which has a capacity of 456,000 acre feet, will serve to irrigate 130,000 acres of land situated about 75 miles east of the Yellowstone National Park

**The grand** total of canal excavation at Panama for the month of December was 2,811 681 cubic yards This is 362,366 cubic yards more than the total for November, but 1,068 656 cubic yards less than the highest record made in March 1909 Of the grand total, 1,455,611 cubic yards was dry excavation, removed principally by steam shovels The dredges removed 1,356 070 cubic yards in addition to the amount pumped into Gatun dam by the suction dredges engaged on that work

**In recognition** of the culmination of his life work in the discovery of the North Pole, the Senate has passed a bill making Commander Robert E Peary a rear admiral on the retired list This signal recognition of the explorer followed closely upon the recent gathering presided over by the Governor of the State of New York at which Peary received a gift of $10 000 which, by the way, he immediately contributed to the proposed American expedition for the discovery of the South Pole

**Major Mason M Patrick** of the United States army speaking on the subject of the construction of an artificial island and additional fortifications near the entrance to Chesapeake Bay, drew attention to the fact that the two largest and fastest merchant vessels afloat to-day could each carry 10 000 men with all their munitions of war, and if unopposed, could land them on our coast in less than one week and he also stated that more than one foreign power possesses a fleet of swift transports which can carry at one time over 100,000 men

**Secretary Meyer** has asked for a large appropriation for the enlargement of the government drydocks to suit the huge battleships now under construction He also asks for the construction of a $2,000,000 drydock at Norfolk, for an additional $1,000,000 for increasing the new dock at the New York navy yard to a length of 700 feet, for an additional $1 500 000 for increasing the Puget Sound dock to a width of 110 feet, and for the enlargement of the width of the Pearl Harbor dock, Hawaii, to the same width, at an increased cost of $450,000

**The new** terminal station of the Pennsylvania Railroad Company at 33rd Street and Seventh Avenue, Manhattan, is so far advanced that it will be practically completed by the end of next month The first service to be put in operation will consist of multiple-unit, standard size, electric trains running to Jamaica, Long Island, over a four-track road, which will soon be increased by the addition of two more tracks This will be followed by the opening of the through express service to the West, which will be operated by the 4,000-horse-power electric locomotives illustrated in our issue of December 18th, 1909

**Were Jules Verne** with us to-day, he would be greatly interested in two instances of rapid travel recorded during the past week A traveler from London to San Francisco won a wager by covering the distance in two hours and thirty-five minutes less than ten days, the trip being made by the "Mauretania" to New York, the 20th Century Limited to Chicago, and the Overland Limited to San Francisco A passenger from Lima, Peru, in making a hurried trip in response to a call to London, left Lima the same day by steamer to Panama, crossed by the Panama Railroad; made close connections with a steamer for New York; and caught the "Mauretania" for England If the ship makes an average passage, the whole trip will have been covered in 19 days.

## AERONAUTICS.

**The first** exclusively aeronautic show to be held in America is open at present in Mechanics Building at Boston A score of full-sized representative aeroplanes of all types, together with a large number of models, are on view Several competitions for models will be held, and some of the gliders and motor-driven aeroplanes may be tried out upon the ice of the lake in Franklin Field This exhibition will give one a good idea of the state of aeronautics in the United States to-day

**On the 10th instant** Wilbur and Orville Wright were presented with the Langley medals of the Smithsonian Institution by Chief Justice Fuller at Washington Dr Alexander Graham Bell and Senator Henry Cabot Lodge made brief addresses Wilbur Wright announced that as soon as he and his brother got their American company under way they expect to devote their time to research work in aviation The two gold medals were designed by J C Champlain a member of the French Academy, the reverse being from the seal of the Institution, which was designed by St Gaudens

**Paulhan** has expressed a willingness to fly in the vicinity of New York if Curtiss or some other interested person will have that injunction dissolved which now hangs over the heads of aviators using warpable planes or hinged wing tips His brilliant success in California leads one to hope that his desire may be gratified in the interests of a sport of which the United States in general and the East in particular knows lamentably little If Paulhan really gives an exhibition in these parts he will do much to stimulate New York's interest in aviation The Hudson Fulton flights were after all a fiasco, and yet they roused New York to an intense pitch of excitement. Paulhan ought to do better

**The first week** of February the suit of the Wright brothers against Paulhan for an injunction restraining him from giving exhibitions in his Farman biplane was tried before Judge Hand in the United States Circuit Court in New York city Judge Hand manifested great interest in the case and his decision is awaited with interest It is uncertain whether he will grant a preliminary injunction as Judge Hazel did at Buffalo last December In defending the attack of the Wrights upon the Bleriot monoplane Mr E R Newell asserted that Prof S S Montgomery's patent which antedates the Wright patent, covers the same system of plane warping as the Wrights themselves claim and he further says that the machine as built to-day does not correspond with the patent A full report of the Wright-Curtiss case and the text of Judge Hazel's decision appears in the current SUPPLEMENT

**As soon** as he had finished flying at Los Angeles, Charles K Hamilton went to San Diego where he made a number of daring flights with his Curtiss biplane On January 23d, after starting from the vast plain near the Hotel Del Coronado Hamilton twice flew out over the ocean so far that he disappeared from view for ten minutes When he reappeared he came from a different direction In the first flight he covered about 10 miles, and in the second one 15 The wind was blowing at times as high as 20 miles an hour After circling upward to a height of about 800 feet Hamilton stopped his motor and made a wonderful long straight glide to earth This is probably a record performance, certainly the longest glide ever made in America. A week later at Bakersfield Cal he made two excellent flights under difficult conditions Starting from a half mile track, he flew about the town and out over the desert and adjoining oil fields, finally landing successfully at the starting point His mastery of the biplane seemed complete

**Subsequent** to the Los Angeles aviation meeting M Paulhan made excellent exhibition flights at San Francisco, Denver, and New Orleans At San Francisco on January 24th he made several flights in a strong wind the last and highest of which of 12 minutes duration, was made after sunset. Two days later he rose to a height of 1,300 feet in a flight of 31 minutes' duration On February 1st, at Denver, he was mobbed by a crowd of 30,000 people eager to see him fly After three preliminary attempts, he finally left the ground and made two circuits of the course at Overland Park The next day he made a 15-mile cross-country flight in a driving snow storm In starting, he ran his Farman biplane through snow three inches deep, and when he alighted, the planes and struts of the machine were in many places covered with snow, while Paulhan himself was suffering from the bitter cold Previous to this long flight, he made a preliminary flight of 8 miles. On February 4th after circling the Park successfully a dozen times, Paulhan twice was unsuccessful in starting in the distance at his disposal The first time one of the wheels of his machine struck the fence and was knocked off while the second time the machine crashed into the fence and was demolished Paulhan was unhurt, but several spectators were injured.

## SCIENCE

**The American Museum** of Natural History in New York city has commissioned William Couper to model a statue of Commander Robert E Peary for the Museum The statue is to be life size and of marble

**In a bulletin** issued by the United States Department of Agriculture Mr Ned Dearborn writes on methods of destroying English sparrows The evidence of the destructiveness of the sparrow is overwhelming, for which reason some means should be adopted to check the spread of the bird Mr Dearborn recommends the destruction of the nests from two to twelve days throughout the breeding season Thus the number of English sparrows could be reduced without resorting to shot poison or traps

**The Smithsonian Institution** has received a letter from ex-President Roosevelt dated December 15th 1909 from Nairobi informing the secretary of that Institution that his expedition has finished its work in British East Africa The collections made in that country aggregate 8 463 animals which include mammals large and small, birds, reptiles and batrachians, fresh water and marine fish Considering the fact that probably over 95 per cent of these animals find their duplicates in the natural history museums of this country and of Europe ex-President Roosevelt seems to have been doing much unnecessary killing

**The Radium Institute** of America has been incorporated Its purposes are to study radium and radio active substances rays, and emanations in the interests of science and humanity and to maintain a chemical laboratory library, meeting room and offices and to acquire and hold patents and licenses to deal in radium and properties pertaining to radium The headquarters of the Institute will be located in New York The twelve incorporators are Dr Robert Abby, Dr Nicholas Murry Butler, Charles F Chandler Bergen Davis, William J Gies, William Hallock, Ellwood Hendrick Hugo Lieber Dr Willy Meyer George B Pegram, Hugo Schweitzer, and Edgar F Smith of the University of Pennsylvania

**An expedition** to observe and photograph Halley's comet from the Hawaiian Islands is to be sent out by the Astronomical and Astrophysical Society of America In view of the possible perturbations arising from the close approach of the comet to the earth on May 1st and to Venus on May 16th to 18th meridian observations are especially desired during the period in which the comet is sufficiently bright for that purpose The close approach of the comet to the earth will afford an unusual opportunity for a study of the physical condition of comets The comet's close proximity to the sun at the time of maximum brilliancy imposes serious limitations upon the Society's programme Widely extended co-operation will be required throughout the whole world if a continuous photographic record is to be even remotely realized

**The American Museum** of Natural History has been presented with a lifesize marble statue of Morris K Jesup by J Pierpont Morgan, Henry Fairfield Osborn, Cleveland H Dodge Charles Lanier J Hampden Robb, Joseph H Choate, and others At the unveiling of the statue addresses were delivered by Prof Osborn (who succeeded Mr Jesup as president of the Museum) Mayor Gaynor and Joseph H Choate

**Commander Robert E Peary** has contributed $10 000 to a fund for the equipping of an American expedition to the South Pole The check for the amount of his contribution had been handed to him by Gov Hughes on behalf of the people of New York as a testimonial of appreciation of his achievement in finding the North Pole, and the Metropolitan Opera House was crowded with people who had come to take part in what the fostering Civic Forum called a "national testimonial" to the explorer

**There is** a gaseous element discovered in the atmosphere by Ramsay which is remarkable for its chemical inertness but though destitute of chemical properties it possesses a very curious physical property which was discovered by J Norman Collie When a sealed glass tube containing mercury in an atmosphere of neon at low pressure is shaken it becomes strongly luminous Similar effects are obtained when other gases are substituted for neon but the light emitted by neon in these conditions is especially bright If the shaking is repeated at intervals during two or three hours, the intensity of the light diminishes for a time and thereafter remains constant The original luminosity can be restored by passing an electric discharge through the tube If one end of the tube is heated to 750 deg F while the other end is cooled by immersion in liquid air and the tube is then allowed to return to the ordinary atmospheric temperature the part which has been heated glows much more brightly than before The luminosity is also greatly increased by substituting a tube of fused quartz for the glass tube G Claude is endeavoring to utilize this remarkable property of neon as a source of light and claims to have constructed neon lamps of an efficiency equal to about 1 watt per candle power.

# DID GREAT BRITAIN HAVE THE FIRST "DREADNOUGHT"?

## THE "ROYAL SOVEREIGN" OF 1862

BY PERCIVAL A. HISLAM

The SCIENTIFIC AMERICAN for November 20th, 1909, contained a description by Mr. William Boerum Wetmore of the U. S. S. "Roanoke," a converted steam frigate, which he claimed to have been the original prototype of the "Dreadnought." The date of the conversion of the "Roanoke" from the frigate into the three-turreted ironclad was 1863, but England, the birthplace of the twentieth century "Dreadnought," has a similar instance to the "Roanoke," but which dates from the previous year—1862.

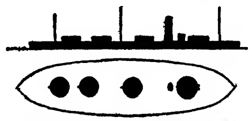
The "Royal Sovereign," as this ship was named, was built as a three-decked sailing ship of 3,144 tons and 120 guns, and in 1860 had been fitted with engines of 800 horse-power. The sides of the "Royal Sovereign" after conversion were composed of three feet of solid timber strengthened internally with diagonal iron bands and clothed externally to some distance below the waterline with 5½ inch rolled armor plates. One inch iron plating was laid upon the deck beams, and over the iron plating was laid the deck proper, consisting of 6-inch and 8-inch oak planking. From the sides of the ship the deck sloped upward to the outer circumference of the turrets, which thus appeared like circular forts on the apex of a glacis.

The following description is taken from a contemporary account in the London Times newspaper: "Stepping on the 'Royal Sovereign's' upper deck, we find that her light iron bulwarks, 3 feet 6 inches in depth, are thrown down outward on hinged stanchions. On the crest of the deck stand the four turrets and pilot house, funnel casing, hatchways, and ventilating shaft. The foremost turret, standing five feet above the deck, has its top covered by a grating, and is surrounded by a handrail, and thus affords a deck promenade for the officer of the watch or lookout man. The single-gun turrets are 4 feet 3 inches above the deck."

It was claimed at the time that the method of mounting and working the guns in the "Royal Sovereign" was superior to anything which had then been applied in any American turret ship. In American designs the turret rested upon the upper deck, and was thus liable to easy disablement, but in the English vessel the base of the turret was on the lower deck, and the citadel was therefore much less likely to be disabled by a hit. The American method resulted in the turret being nine feet above the deck, while in the "Royal Sovereign" only five feet or four feet three inches, as the case might be, was exposed to the enemy's fire. Further, the latter ship's turrets could be worked by rack and pinion inside the turret, by the same method from the outside, and by handspikes worked like capstan bars, as well as by steam.

It will be seen that the "Royal Sovereign" had four turrets—one more than the "Roanoke", but she had one gun less, for while the foremost contained two guns, the others had only one each. All the turrets were mounted on the center line of the ship, and the guns were muzzle loaders of 12½ tons firing a 300-pound shot.

The original speed of the "Royal Sovereign" had been 12.25 knots, but after conversion this fell to 11, a difference which was fully accounted for by the increased immersion of three feet. Her freeboard remained at seven feet after conversion. The cost of the work was $690,900.



Converted British three-decker "Royal Sovereign" changed to an all-big-gun battleship in 1862

WAS THIS THE FIRST "DREADNOUGHT"?

The "Royal Sovereign," besides having been, at any rate, one of the prototypes of the modern "Dreadnought," is interesting as having been the first vessel in which the turret principles of Capt. Cowper Coles were put into practice. The first vessel actually built in England embodying those principles was the "Captain," an ironclad of 4,272 tons, which capsized in the Bay of Biscay on September 6th, 1870.

According to contemporary accounts, the speed of the "Roanoke" was only 5 knots. This is inferior to the "Royal Sovereign's" speed by 6 knots. The latter vessel, again, had four turrets to the "Roanoke's" three; both ships had 5½ inches of side armor in a rolled plate, although up till then most American ships had been armored on the inferior laminated system; both ships were practically mastless, for the three poles of the "Royal Sovereign" reached only just above the top of the funnel. In freeboard there was little to choose between the two, while in the method of placing the turrets the British ship was decidedly superior.

Much, therefore, as we owe to America in the development of modern navies, and more especially, perhaps, in the introduction of steam navigation and in the correct placing of turrets in modern battleships, I think it must be admitted that Great Britain was the first to possess a prototype of the modern "Dreadnought."

I have been unable to procure a picture of the "Royal Sovereign" for reproduction, but the accompanying elevation and plan will convey an idea of the appearance of the ship.

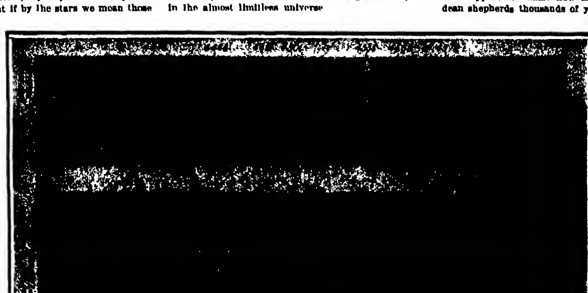
It may be mentioned that Russia launched in 1867 the "Admiral Lazareff," a three-turreted ironclad of 3,754 tons, very similar in general design to the "Roanoke." She carried in each turret two 15½-ton guns, but it was seen fit later to alter this to one 11-inch for each. In view of the diagonal (or echelon) arrangement adopted in the British "Dreadnought" cruisers of the "Invincible" type, it is interesting also to note that Italy led the way with this system of mounting with the "Duilio" (1876), Great Britain following with the "Inflexible" in 1881, and with four other ships a few years later. The only American examples of this system of mounting were seen in the "Maine" and "Texas," the first with two 10-inch and the second with one 12-inch gun in each turret.

The arrangement of the turrets in the British "Dreadnought" had a prototype in the French "Admiral Duperré," launched in 1879. This ship had two turrets on the center line and on the same level aft, and a turret on each beam just forward of the funnels. The guns had a freeboard of 27 feet 5 inches, giving them a great command of fire. Each turret contained one gun of 13.5 inches caliber, and if another center-line turret be added forward of the two beam turrets, it will be seen that the arrangement of the "Dreadnought" is almost exactly reproduced. It is strange how often we are confronted with the fact, in reading old books and other records, that there is "nothing new under the sun."

# OTHER WORLDS IN SPACE

BY PROF. S. A. MITCHELL, COLUMBIA UNIVERSITY

If one should look at the heavens on any clear moonless evening, he would see them shining with countless orbs of light apparently millions in number. It is a fact that from our earliest education we have regarded the terms "numberless as the sands of the seashore," and "countless as the stars," synonymous with quantities almost infinite, but if by the stars we mean those that can be seen by the naked eye (and the expression originated thousands of years before the invention of the telescope), our ideas have been utterly at variance with the truth. The unaided eye cannot see millions of stars as is commonly supposed, nor yet hundreds of thousands, for at any one time we could count only two to three thousand separate stars, and in the whole heavens there are less than six thousand which can be seen without a telescope. A small glass, however, increases this number largely, and with greater and greater telescopes more and more stars are brought to our ken. It is estimated that the astronomer of to-day can see and photograph upward of a hundred million of stars. Each of these is a sun shining by its own light; the new astronomy tells us that thousands of these suns have systems around them possibly resembling our own solar system, and it is not outside the bounds of probability that many of the planets about these distant suns may be inhabited by people who live and move and think. Indeed, this earth of ours, of so much importance to us, is a most insignificant speck in the almost limitless universe.



PHOTOGRAPHS OF THE SPECTRUM OF μ ORIONIS, JANUARY 5th AND 8th, 1906.

The upper spectrum shows a velocity of 25 miles per second away from the earth, and the lower one of 48 miles per second in the same direction.

Astronomers by their meridian circles have been able to measure the exact positions of these distant so-called "fixed" stars, and have come to the conclusion that in spite of their names, there is none of them absolutely fixed in space, i. e., without motions. The movements of these heavenly bodies at the enormous distances we are from them are however very small, and the changes of position in the sky so slight from year to year that they could not be found without the most careful measurements. So from this point of view the stars are fixed, and the constellations appear the same now as they did to the Chaldean shepherds thousands of years ago. Still the motions are there none the less. The old astronomy was able to measure motions athwart the sky, at right angles to our line of vision; the new astronomy is able to supplement this by a knowledge of their movements toward us or away from us in the line of sight. The revelations of this new branch of astronomy are revolutionary in their importance, and of the greatest moment to our ideas of the universe as a whole.

The principles underlying the use of the modern spectroscope applied to the stars are given in SCIENTIFIC AMERICAN, December 25th, 1909. There is required for this purpose a powerful telescope, and a most accurate spectroscope attached, whose temperature must be kept absolutely uniform during the two or three hours that may be consumed while the photo-

(Continued on page 170.)

# CONCRETE CONSTRUCTION ON THE PANAMA CANAL

## HOW THE EIGHT MILLION CUBIC YARDS OF CONCRETE IS HANDLED

To the untrained eye the work which has hitherto been done on the construction of the Panama Canal necessarily appears more or less confused and chaotic. Although over one-half of the excavation has been completed, very little if any of the prism of the canal has been excavated to its finished dimensions, and the outline of the completed work is therefore irregular and ragged.

Some few months ago, however, the work of putting in the permanent concrete structures began, and from now on this great work will begin to take on definite shape and present visual evidence of its massive and permanent character.

The masonry works will not only be the largest of their kind ever built, the locks and spillways being on a scale of unprecedented proportions, but these works in the aggregate will probably represent the largest mass of masonry of any kind whatsoever hitherto placed in a single engineering work of magnitude. It is questionable whether an exception would have to be made even in the case of some of the famous masonry aqueducts built in ancient times, and the Pyramids or the Great Wall of China are not to be seriously reckoned in comparison with difficult hydraulic works of the character of those on the Panama Canal. In the accompanying series of photographs, which were recently taken on the Isthmus, one is able for the first time to gain some impression of the massive character of the concrete and reinforced-concrete structures the construction of which is now proceeding with gratifying rapidity.

The concrete work embraces six huge locks, three at Gatun on the Atlantic side of the Isthmus, one at Pedro Miguel and two at Miraflores on the Pacific side, and the great spillway in the center of the Gatun dam for carrying off the surplus waters. All of the locks will be 110 feet wide by 1,000 feet long, with a depth over the sills of 45 feet. The three locks at Gatun will form a continuous structure which, with the piers forming the approaches at each end, will have a total length of 3,800 feet, the whole work forming one huge monolithic mass of concrete. The Pedro Miguel lock with its piers will be 1,800 feet, and the two locks and piers at Miraflores will have a length of 2,800 feet. Into the construction of these locks will enter about 8,000,000 cubic yards of concrete, and of this 900,000 tons will consist of cement. The spillway through the Gatun dam has been cut through a low

Note the wooden forms in which the walls are molded.
**Building concrete side wall—Gatun Spillway.**

Millions of tons of sand are needed for the concrete.
**Sand cranes and pockets at Balboa.**

**CONCRETE CONSTRUCTION ON THE PANAMA CANAL.**

hill situated at about the center of the dam, and within the excavation thus formed is now being laid the deep concrete flooring, the massive retaining walls and the piers between which will swing the gates for regulating the height of the water in that great artificial inland sea which will be formed by the dam

It can readily be understood that the economical and expeditious laying of 8 000 000 cubic yards of concrete in structures of this magnitude called for a special plant of great size and capacity At Gatun about 4,000 000 cubic yards of concrete will be employed The crushed stone the sand and the cement for this concrete is handled in the following manner The crushed stone comes from Porto Bello a small hamlet about 20 miles east of Colon along the Atlantic coast The rock is taken from the quarry by steam shovels and sent by gravity to the giant crushers, and thence by gravity to the barges in the harbor From this point it is carried to Cristobal at the Atlantic entrance to the canal and thence via the old French channel, to the docks at Gatun Here it is unloaded into storage bins by giant grab buckets, operated from cableways suspended between two sets of towers on either side of the channel

The sand is brought from Nombre de Dios, about 40 miles along the coast from Colon It is taken from the sand pits by clamshell buckets, loaded into steel barges and taken to Gatun, where it is unloaded by a process similar to that of unloading the crushed rock The cement is now being shipped from New York At Colon the cement is transferred to barges and taken via the old French channel to Gatun and unloaded to the storage yards The rock and sand storage piles have a capacity of about 300 000 cubic yards, while the cement yard accommodates about 100,000 barrels From these storage buildings, the rock, sand, and cement are delivered through valves to charging cars running underneath These cars, which are electrically operated, carry the materials to the concrete mixing machines located nearer the locks' site and discharge it direct to the machines After the concrete is mixed, it is dumped into buckets set on flat cars, and the cars are run to position under the wide cableways spanning the locks' site and from these cableways the buckets filled with concrete are swung to position on the locks under construction

The general principles upon which the plant at the locks on the Pacific side is designed are the same as those employed at Gatun, the mechanical details have been varied to meet the local conditions

The latest report of the work, namely, that for December last, shows that during the month the total work of excavation amounted to 2,618,662 cubic yards and that the total canal excavation of all kinds amounted to 2,811 681 cubic yards The material placed in dams, mainly at the Gatun dam amounted to 340,610 cubic yards, and during the month 57,265 cubic yards of concrete were built up in place

### HALLEY'S COMET

Some interesting measures of Halley's comet, made with the micrometer of the Yerkes 40-inch refractor, are published by Prof Barnard in No 605 of the Astronomical Journal With this large telescope the comet was quite an easy object, and the measures should be good, but, as Prof Barnard suggests, the edges of such a nebulous body are not easy to set on

The measures extend up to November 30th, 1909 when the estimated magnitude was about 11 0, and the comet showed a condensation of some 7 inches diameter The diameter of the whole object was 41 inches, and possibly an ill-defined nucleus was seen, but this feature was very doubtful From September 17th to November 14th the measured diameters reduced to miles ranged from 16,400 to 200 miles the mean being 12,800 miles, or about 1½ times the earth's diameter

At the December 1909 meeting of the Royal Astronomical Society reported in No 418 of the Observatory the Astronomer Royal announced that a photograph secured with the Reynolds reflector at Helwan, on August 24th shows the comet's image, its position agrees within 0 12s in R A and 1 7 min in declination with the position calculated from the Cowell Crommelin orbit corrected by the Greenwich observations Messrs Keeling and Knox Shaw are to be congratulated heartily upon securing the first known photograph of the comet In No 25 of the Gazette astronomique, Signor Pio Emanuelli discusses the probable encounter between the earth and the comet's tail in May next At 10 A M (G M T) on May 18th the comet will pass the descending node of its orbit, while the earth will pass the same point eighteen hours later For an encounter between the tail and the earth to take place, it is shown to be necessary that the latter should be 22,100 000 kilometers (13,732,277 miles) long and that its breadth should be such that it extends, from its axis earthward, 400 000 kilometers (2 485,550 miles)

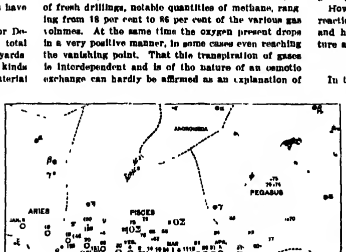
The accompanying chart shows approximately the apparent path of the comet, according to Mr Crommelin's ephemeris up to April 5th - Nature

*The sluiceways, etc., for rapidly emptying and filling the locks are of unusual size.*

**WOODEN FORMS FOR GATUN LOCK CONDUITS.**

### The Occluded Gases in Coal.

Prof S W Parr and Mr Perry Barker of the University of Illinois have made an elaborate study of occluded gases in coal, which is published in a bulletin recently issued by the university As a result of their work it seems that two active processes are set up immediately upon the liberation of the coal from the vein The first is an exudation of hydrocarbons, mainly consisting of marsh gas ($CH_4$), the second is an absorption of oxygen There can be little question, moreover, that the alterations proceed simultaneously There are present in the gases from all the samples of fresh drillings, notable quantities of methane, ranging from 18 per cent to 86 per cent of the various gas volumes. At the same time the oxygen present drops in a very positive manner, in some cases even reaching the vanishing point. That this transpiration of gases is interdependent and is of the nature of an osmotic exchange can hardly be affirmed as an explanation of the phenomenon On the contrary, there seems to be evidence that the gases operate independently of each other



**APPARENT PATH OF HALLEY'S COMET FROM JANUARY 5th TO APRIL 5th.**

In the case of samples of marsh gas the exudation of $CH_4$ seems to have spent itself in those samples held in laboratory containers for two years. In no case is there evidence of further liberation of this gas, even with thorough application of the vacuum An evacuation of the gases from two-year-old samples shows no marsh gas present. The completion of this exudation would seem to be reached after two months, though it is well to note that by forcing, as with a vacuum, the two-months-old sample may be made to yield more methane, though in relatively small quantities. On the other hand, the avidity of the coal for oxygen seems to be pronounced at the very beginning of the exposure of the freshly-mined material, and while there are a number of cases where a certain agreement seems to exist between the in-going and the outgoing marsh gas, still there are more cases where the absorption of oxygen is pronounced without any evidence of marsh gas being present. In all cases the oxygen nitrogen ratio shows a positive diminution of the oxygen from the normal ratio of approximately 1 to 4 with practically no evidence of marsh gas being present It seems fair to conclude, for the present, that there is no necessary connection, at least of a strictly chemical nature, between the exudation of marsh gas and the absorption of oxygen

Again, the liberation of $CH_4$, while very active in the first few days after removal of the coal from the ground, diminishes in amount quite rapidly till, after the second month, there is very little of this gas in evidence The activity of the coal for oxygen, on the contrary, seems to be of longer duration Samples collected June 1st, 1906, were tested in May and June 1908 There is marked absorption of oxygen in the sample after two days' exposure in the flask to normal air, while in a second, with five days' exposure, a still further reduction in the oxygen ratio without accompanying evidence, also, it should be noted, of marsh gas, was obtained A marked avidity for oxygen was shown after two years from the time of collecting

These facts have a direct bearing on the topic of deterioration as substantially defining the limit as to time of that form of alteration While varying somewhat in different coals, the loss of hydrocarbons for the most part is practically complete at the end of two months These facts have a bearing also upon the matter of weathering, and indirectly upon the matter of spontaneous combustion The absorption of oxygen is undoubtedly closely associated with both of these phenomena The studies upon the weathering processes coincide with these studies in gases, namely, that in all probability this low type of oxidation extends over an indefinite length of time Moreover, while under normal conditions there is effected but a very slight oxidation and loss of fuel values, the conditions are favorable, as, for example, for bringing about a very rapid combination with oxygen upon an increase of temperature

How far this absorption of oxygen is a chemical reaction, or low combustion resulting in $CO_2$ and $H_2O$, and how far an absorption into the molecular structure and composition of coal must be left for study

### Dying Pearls.

In the Museum of the Louvre in Paris lies a collar of pearls at the point of death! Its deathbed is a plaque of velvet, and it is the large collar that was part of the personal estate of Thiers and once belonged to his wife It is simply set and has no artistic value, its material value, however is estimated at $60,000 It consists of 145 pearls in three rows, the total weight of which is 2,097 grains, the three largest pearls of the collar weighing 36, 39, and 51 grains respectively. This collar must "die", every day it loses another degree of its luster, and in the course of the present decade it will become as dingy as a much-worn wreath of roses

Why? Because pearls keep their incomparable sheen only when worn by women and come into habitual contact with the gentle, soft, and warm skin of the wearer When, for instance, Queen Augusta died it was found that her magnificent strings of pearls were likewise in a persistent decline, and for the reason, indeed, that for many years she had not worn them on her bare neck (which fact was explained by her age) but only around the fabric of the neck of her waist. At that time a treatment of baths in sea-water was prescribed for them by experts, and for several months, under obvious necessary precautions, they were sunk into the sea and thus recovered their old luster

When, for instance, a collar of pearls is taken from the neck, where, subject to a temperature of 40 deg C. approximately it has lain for hours, and is laid upon the marble plate of the dresser, which is perhaps only 20 deg. C warm, it feels, so to speak, a

## MR. RIEDERER'S PROBLEM.

To the Editor of the SCIENTIFIC AMERICAN

Your correspondent who replies to my problem certainly has not studied the question very closely There is absolutely no doubt as to the possibility of the solution for taking any single number, it is quite evident that the remaining 14 numbers will make 7 pairs, each one of which with the taken number forming a different combination of three What one number is capable of doing, every other is likewise. So that certainly proves that 7 combinations as told are possible The question is, how can this or any other similar problem be worked out without a haphazard shifting till you got the solution?

Find the system The problem is all right

New York city HERMAN S RIEDERER, Ph D

## OBSERVATIONS OF A METEOR IN FLIGHT

To the Editor of the SCIENTIFIC AMERICAN

I have seen no mention in the newspaper of the meteor that fell west of Corrington, North Dakota, on January 10th. It was seen for seventy miles south of Streeter, North Dakota and passed over us with great speed. It buried itself six feet in the ground about seventy miles north of Streeter The heat produced was so great that for forty-eight hours no one could approach it closely notwithstanding the fact that the ground was covered with snow and was frozen to a depth of four feet When the meteor passed over our heads from a southwesterly direction to northeast, it shone most brilliantly The noise which it produced can be likened only to that of a very large cannon ball in flight The diameter of the meteor is 56 inches It has been taken out and sent to Bismarck J J ROTT

Streeter, N D

## SOME STRANGE ANIMAL INSTINCTS.

To the Editor of the SCIENTIFIC AMERICAN

Two items in your science column of January 8th, 1910, interest me That about the return home of the kitten and cat because there are scientists in your own city and elsewhere who have held doggedly that the special sense of this wonderful ability to go back home is not a special sense but the result of some sort of observation, although the cat may be blind folded They even claim that homing pigeons find their way back by observing 'the lie of the country' While this instinct is by no means unerring, and is developed to a much greater extent in some individuals than in others, there seems no justification of the denial to these lower creatures of a faculty of orientation or traversing which man possesses in only a small degree There are many instances where the return has been made over a route very different from that of the outgoing journey and could not have been influenced by the topography, even if it could have been observed

The other instance is that of the magpie which was fond of rubbing tobacco and its ashes into its plumage as mentioned by the writer in Kosmos This is of special interest to me because I had made a similar observation on a bluejay—a relative of the magpie—and had never so far been able to confirm it from any other source Fortunately as long ago as 1896 I recorded it in my little book "The Story of the Birds" (Appleton) from which I venture to quote

"I saw him (the jay) engaged in the walnut tree one day in late summer in a manner that made me fear that his bath had not been sufficiently effectual He would pluck off a leaf, lift his wing and rub it into his plumage I saw him do it repeatedly, and since walnut trees have a pungent odor and are disagreeable to insects, I feared that he had some guests that he was trying to get rid of If this theory should be correct here was a case of a bird using perfumes with at least good intentions" (Page 243)

It is well known that dogs and other mammals will rub their bodies into ur against something that is strikingly odorous, for the sake of the perfume only in which they seem to delight, but these two are the only instances that I know of where birds are recorded as doing the same. It would be interesting to hear from any other instances—if there are any, as is likely JAMES NEWTON BASKETT

Mexico, Mo

## RE-ARMING OUR WARSHIPS.

To the Editor of the SCIENTIFIC AMERICAN

In a letter to the SCIENTIFIC AMERICAN of September 5th, 1908, a correspondent, Mr A. B Wingfield, suggested the re-arming of our "Connecticut" class of battleships with four 12-inch guns in place of the eight 8-inch that are now carried in the main battery of this type. The Editor's comment at the time was that the greater weight of 12-inch gun emplacements on the beam would necessitate too costly structural strengthenings to justify the change, that the 6-inch armor protection would be too light for these emplacements, and that the increase in dead weight would sink the already low armor belt even lower in the water A previous letter appeared in your issue of August 15th, 1908, and since then changes of this character have been under consideration

I know that if the SCIENTIFIC AMERICAN takes up this matter, its influence will be brought to bear on naval men, the object in view, of course, being to make dreadnoughts of the "Connecticut" type and semi-dreadnoughts of the 'Georgia" class. The younger officers in the navy whom I have questioned in regard to this matter are unanimously in favor of these improvements.

As armed at present, the "Connecticut' and "Georgia' classes are not as efficient as a comparatively small additional expense could make them, and in view of the conceded superiority of the all big gun type of ship, it seems worth while to consider how it would be possible to so reconstruct the above types as to make them more formidable against dreadnoughts.

The pre-eminent function of a battleship is to concentrate the greatest efficiency and power possible in a single vessel The armament of the "Connecticut" class consists of four 12-inch eight 8 inch, 12 7-inch, and twenty 3 inch, of which four 12's, four 8's, six 7's and eight 3s can fire on broadside The "Georgia" type mounts four 12 inch, eight 8-inch, twelve 6-inch, and twelve 3 inch, of which four 12's six 8's, six 6s, and six 3's fire on broadside Now to convert these ships to dreadnoughts it would be necessary to mount one 12 inch gun in place of the two 8s in each of the beam turrets keeping the emplacements as they are

As the 7 inch guns are too small for battle ranges and too slow for torpedo defense they could be substituted by the 5-inch rapid fires which are now being mounted on all our new dreadnoughts. With say eighteen of these and a few more 3 pounders in place of the present twenty 3 inch guns, the change is complete and you have a vessel the equal of the "Michigan' type which are really powerful dreadnoughts on a "Connecticut' displacement

In the "Georgia' class the same renovations could be made, except that the four superposed 8's would have to be retained and the six additional 6's omitted The 'Idaho' and "Mississippi" could be similarly treated Under this arrangement the armament of the two classes would now be "Connecticut" eight 12 inch and eighteen 5-inch with a broadside fire of six 12s and nine 5's "Georgia" six 12 inch, four 8 inch, and twelve 5-inch with a broadside fire of five 12s, four 8's, and six 5s Then our two 'Idahos, four 'Georgias," six "Connecticuts" two 'Michigans" and two "Delawares" would mount 124 12 inch guns instead of 84 as at present, and would practically be a dreadnought fleet The benefits from these changes are as follows

1 A homogeneous broadside giving greater concentration of fire at battle ranges

2 A simpler system of spotting and fire control, with only one range to get and only one caliber of gun (excepting the four 'Georgias") in the main battery

3 A greater efficiency of ordnance resulting from more uniformity in ammunition and consequent speed in handling

4 A better organization for and the quicker delivery of shell

5 An opportunity offered to hold former 7 inch gun crews in r serve for turret crews

6 The elimination of unwieldy and inaccurate middle batteries with large crews necessary to their service in exposed positions

7 A smaller number of men in action at the same time and behind heavier armor (i. e., turrets only) at battle ranges

8 An increase in the efficiency of torpedo defense by a gun more practicable in every way than the old caliber, which was ineffective at 3 500 yards and required the same number of men to handle it

9 The lightening of the armor belt and bringing it higher out of the water, where it belongs

10 The placing of the entire main battery behind turret armor

Now as to the cost For one battleship of the "Connecticut" class to be improved as shown above, the expense would consist chiefly of the price of four 12 inch and eighteen 5-inch rifles, and the remodeling of the 8-inch turrets and handling rooms The 5-inch guns could occupy positions behind the old 7 inch barbettes, on the gun deck the 7 inch casements (slightly enlarged) on the main deck and new mounts for the superstructure I do not believe that the structural part of the ship would need strengthening in any way Moreover, all these discarded eights, sevens, sixes, and threes could be mounted on smaller cruisers, where they could do the work required of them, and thus money on new construction could be saved

I think that you will agree with me in saying that with these improvements made our pre-dreadnought type will not only possess far greater efficiency than they do now, but also that they will be able to stand in the first line of battle with future dreadnoughts The real question is this Is this greater efficiency worth its cost? In view of the slight difference in the cost of maintaining in commission a "Connecticut" and a "Delaware," I think it is and the SCIENTIFIC AMERICAN can do a lot toward making these paper changes realities. HAROLD M KENNARD

Brooklyn, N Y

[In publishing this interesting study of a much mooted question, we would point out that it seems to be the unanimous opinion of naval men in all navies that the re-arming of the older ships does not pay, that all appropriations for construction should be put into new ships. Such changes as are suggested above would involve enormously costly structural work on the hulls There is no room for 12 inch guns in the 8 inch turrets —ED]

## The New Supplement Catalogue

The publishers of the SCIENTIFIC AMERICAN have issued a new catalogue of the SCIENTIFIC AMERICAN SUPPLEMENT in which 20,000 articles are listed Many of these articles have been translated from foreign publications which are ordinarily inaccessible to English-speaking readers Many of them also are papers read before the learned scientific societies of the world and accessible only in a few large public libraries The articles are all carefully indexed so that the best information on any particular scientific subject may be found in a few minutes. The catalogue will be sent gratuitously to all who apply for it

## The Current Supplement.

The current SUPPLEMENT, No 1781 contains some remarkable pictures of the Seven Wonders of the World, together with a good article on them "The Practical Utilization of Insect Parasites" is the title of an article which will interest the farmer Another installment of the Munroe and Hall paper on "Combustion and Explosion, a Primer on Explosives for Coal Miners' is published Some new uses of paper are described Mr D A Arthur contributes an article on Chinese calendars Since the Chinese have just celebrated their new year, this article comes out with particular timeliness H A Humphrey's paper on an internal-combustion pump is concluded Leonardo da Vinci, perhaps the only truly all-around genius of the world, is the subject of an excellent article by Edward P Buffet The Wright injunction is summarized and illustrated

## Comets Due to Return This Year.

In addition to Halley's, two other comets are due to pass through perihelion this year The first is known as Tempel's second periodical comet, discovered in 1873 July 3rd at Milan Its period is about 5¼ years, and it was re-observed in 1878, 1894, 1899, and 1904, making its perihelion passage, on the last occasion, in November, it should therefore return this coming spring D'Arrest's comet, discovered in 1851, is the second object, and is due to return during the summer of this year Its period is about 6½ years and it was re-observed at its return in 1857, 1870, 1877, 1890 and 1897 but it escaped observation, being unfavorably placed, in 1903

Mr Lynn, who gives these particulars in No 418 of the Observatory also recalls some of the historic occurrences which have coincided with the returns of Halley's comet.

## The Scientific American Fourth Dimension Book.

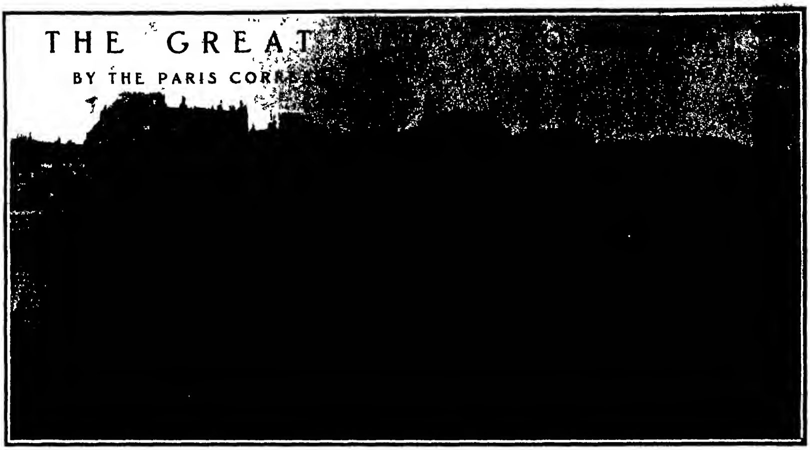
The readers of the SCIENTIFIC AMERICAN have hardly forgotten the SCIENTIFIC AMERICAN'S Prize Competition for the best simple explanation of the Fourth Dimension The prize of $500 was awarded to Lieut-Col Graham Denby Fitch, U S A His essay was published in the SCIENTIFIC AMERICAN for July 4th, 1909 and three others which were accorded honorable mention by the judges followed in successive issues

It seemed to the judges that of the 245 essays submitted, a certain number showed more than passing merit Inasmuch as the popular literature on the subject is by no means extensive, the publishers decided to intrust to Prof Henry P Manning of Brown University, one of the judges the task of selecting some of the best contributions This Prof Manning has done These essays together with the essays which were awarded the prize and honorable mention, are now published in a book which has just been issued by Munn & Co publishers of the SCIENTIFIC AMERICAN An elaborate introduction is provided by Prof Manning, in which he critically and yet simply discusses fourth-dimensional geometry and gives an excellent bibliography on the subject The book sells for $1 50 and can be ordered through any newsdealer or bookseller

The deepest coal seams mined in America lie above a depth of 2 300 feet some of the coal mines in England are developing seams at a depth of 3 600 feet while coal mining is carried on at a depth of about 4,000 feet in Belgium.

# THE GREAT

BY THE PARIS COR



The Seine near the mint.

The inundation of Paris made many of the streets of that metropolis as navigable as the canals of Venice The highest point reached by the water was 31 feet 4 inches above the normal at the Pont Royal Not since the historic flood of 1615 has Paris been visited by such an inundation On January 29th the waters began to fall, and the city for the first time began to feel safe Even as it was, the Seine was swollen to thirty times its ordinary volume and the current raced to the sea twenty times faster than usual The banks have been overflowed for from half a mile to a mile on either side That vast and wonderful sewer system which figures so dramatically in Victor Hugo's "Les Misérables" and which has been dwelt upon time and time again in every guide book of Paris, and that intricate system of subways which handles the vast traffic of Paris, have both played their part in this catastrophe They served as conduits for the flood Huge as they are, they were unable to cope with the turbulent waters Pavements were pressed upward, and the water bubbled up into the streets Apprehension was felt for the safety of the monuments of the French capital, an apprehension which is not yet stilled It seemed almost certain that their foundations would be sapped It speaks well for the work of French engineers that none of the twenty four bridges that span the Seine was carried away, and that it was found necessary to close but eight of them On the other hand, these bridges undoubtedly helped to dam the waters and to aid in the city's inundation It speaks well for the architects and masons of the middle ages that the famous Cathedral of Notre Dame should have stood in a lake for days and days without suffering injury Many of the historic buildings of Paris were flooded, but fortunately the art treasures seem all to have been preserved with little or no injury When the saturated ground dries out and contracts, it may be that some of the buildings will settle and possibly collapse The Louvre, although flooded, was still able to serve its function of housing its priceless paintings and its statues The great shops could not be opened on account of the water The famous Theatre Français still gave its performances, but it used candles as it did back in the days of Molière

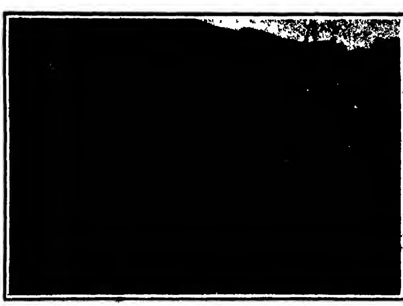
It was but natural that the Chamber of Deputies should have continued its sessions An exhibition of fright on the part of the legislators would undoubtedly have heightened the public terror As it was, the members were ferried across the square to the chamber The old Latin Quarter and the Champ de Mars, the Rue Royale, the Boulevard Haussmann, the Place de la Concorde, the Champs Elysées were swamped

Naturally the subways suffered heavily Only the Gare du Nord seems to have escaped. The station of St. Lazare seems to have suffered most severely As it was, the suburban traffic was entirely cut off, so that the sparing of the Gare du Nord served simply to give the frightened populace a place of questionable refuge Fortunately the waters rose so gradually that the inhabitants of the sewers (the theme of many a thrilling French short story) and of the basements and sub-cellars of Paris were able to escape. Suburban towns lying somewhat lower than the city have suffered The breaking of a dyke completely inundated Gennevilliers. Its community of 10,000 persons was driven out by ten feet of water

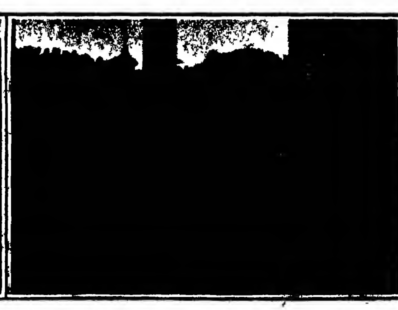
Paris may now be considered safe from water, but the danger from sickness still prevails The stench of the stagnant water and of the drowned animals will undoubtedly continue for days. The Paris health authorities will find difficulty in coping with that situation

The actual cause of the flood has not been fully revealed Some explain it geologically by arguing that the basin of the Seine had become saturated during a mild winter, characterized by heavy rains and little evaporation It will be safer before accepting this theory to await the investigation of the municipal engineers. Only when the floods have subsided and a careful examination can be made, will the full measure of the disaster be ascertained The accounts of bursting sewers and subways and caving streets point indubitably to the necessity of reconstructing much of the famed Parisian sewer and subway systems. It will probably be months before Paris will conduct business as it did before the flood

The engineering aspects of the flood have been sufficiently discussed in our editorial of February 5th. For that reason the results of this Parisian inundation need not here be dwelt upon again It is clear that either the channel of the Seine must be widened by dredging, by the removal of river piers, or by the inordinately expensive construction of an artificial waterway around the city, a waterway which will serve the purpose of diverting the surplus of the Seine in time of flood and of discharging it below the city.



The gondoliers of Paris.



A cart-ferry in one of the streets.

SCENES OF THE GREAT FLOOD.

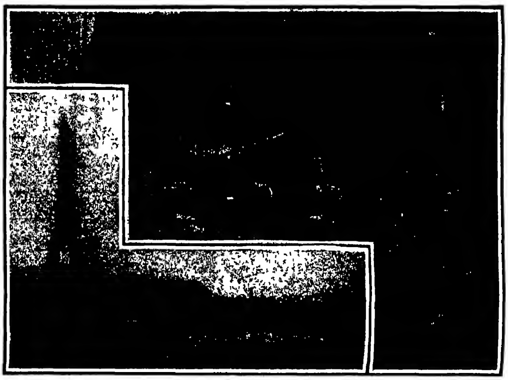
**Reclamation of the Friedeburg Peat Bogs.**

The total area of the peat bogs and moors of Germany is more than 3,000 square miles, of which about two-fifths are situated in Hanover and Schleswig-Holstein. The Prussian government possesses in East Friesland nearly 40,000 acres of upland moors, of which about 16,000 acres, known as the Aurich, or Friedeburg bogs, have for some years been the scene of an attempt at reclamation, which is being carried on with great skill and energy, though unfortunately with a degree of secrecy which makes it difficult to ascertain the exact facts, although the undertaking is of the greatest and most general importance. It is contemplated not only to reclaim the moors for cultivation and settlement, but also to make them the source of energy which will supply electric current for light and power to the surrounding region within a radius of thirty miles. Electric light, thus obtained, is already supplied to Emden, Wilhelmshaven, and several other cities and towns, and large quantities of ammonia, hydrogen sulphide, and other gaseous products are sold for use in various industries. The district to be reclaimed lies between the Ems-Jahde canal on the north and the Nordgeorgsfehn canal on the south, between which a connecting canal will be constructed. Short canals will connect the system with the canals of the older moor colonies to the westward. In all, 38 miles of new canals will be required. Their construction will necessitate the stripping of about 650 acres of moor, from which it is estimated that nearly 250 million cubic feet of peat will be obtained. If this work were done by the old Dutch method, the canals would not be finished in several decades, during which period the price of peat, already very low in this district, would continue to decline. Both of these difficulties were avoided simultaneously by the adoption of electrical methods, by which the work of excavation is carried on very rapidly and supplies its own fuel. In the center of the moor is a boiler plant, which consumes peat exclusively. The problem, of course, will be still more simplified when a method of producing electricity directly from heat is developed.

The first settlers established on the Friedeburg moor will carry on what is known as surface cultivation, and will at the same time gather peat, which they will sell to the electrical company, the charter of which runs for seventy-five years. As the high moor is thus cut down the method of cultivation will be gradually changed to that which is employed in the low-lying moors of Holland.

All of the energy is supplied from the central power station of the Siemens-Schuckert Company, situated on an island in the bog at the intersection of two main roads. From this point wires, supported by poles, radiate in all directions, supplying light and power to the whole country for many miles around. The main canal is bordered by several rows of poles and wires, one for the telephone, another for the peat-digging and agricultural machinery, a third for the high-tension alternating-current long-distance service. Current was to be supplied to the surrounding cities in November of this year. The station is equipped with two steam turbines of 1,800 horse-power each. The great plows used for the excavation of the canals have long been driven by electricity. The peat dug each day is compressed by electric presses into 4,000 blocks, which when dry are used as fuel in the central station. In the gas generators 40,000 cubic feet of fuel gas and 30 pounds of ammonium sulphate are obtained from 100 pounds of peat. The combustion of this quantity of fuel gas generates 273 horse-power hours of energy, while the sale of the ammonia compounds pays a good interest on the capital invested. Contracts for supplying light and power to most of the surrounding towns and cities have already been signed. The duration of the contract in most cases is forty years, while the charter of the Siemens-Schuckert Company will remain in force seventy-five years. The area assigned for cultivation and settlement comprises about 17,000 acres. The digging of the canal requires the peat to be removed from a strip about 150 feet wide, so that the construction of the 38 miles of canal will involve the stripping of 650 acres. The average depth of the peat is 11½ feet. Deducting the superficial stratum of 30 inches, which is comparatively worthless, the digging of all the canals will produce about 247 million cubic feet of peat, which when dried will furnish 1 1/3 million tons of fuel peat. This amount of fuel alone would supply the central station, producing five million kilowatt hours of energy for sixty-six years. On each side of each canal, a strip 165 feet wide is to be cleared of peat for cultivation and settlement. The peat thus obtained, added to that obtained from the canals, would enable the capacity of the station for the duration of its charter to be tripled.

An idea of the cost of the electric light and power thus furnished may be gained from the contract recently concluded with the town of Baut, in which the price of lighting current is fixed at about 10 cents and that of power current at 5 cents, per kilowatt hour. At these rates a 16-candle carbon incandescent lamp or a 40-candle metal filament lamp would cost about ½ cent per hour and an arc lamp from 2 to 6½ cents per hour according to its candle power. Thus the Friedeburg bogs are to be utilized as a field for colonization, as a source of light for the surrounding country within a radius of 30 miles, and as a cheap and reliable source of power for all the cities and farms of East Friesland. Although all the hopes which have been built on the enterprise may not be fulfilled, it is already certain that the reclamation and cultivation of bog land has entered upon a new and promising stage of development in consequence of this application of electricity. It must be admitted, however, that on the Friedeburg moor the conditions for reclamation are especially favorable. The land is in general level, and it has already been superficially dried and smoothed by burning. The roads through the moor are already bordered with rankly-growing grass.



Scenes from the great Paris flood.

**Peary a Rear Admiral.**

Commander Robert E. Peary has been made a rear admiral of the highest grade and with maximum pay, so far as the Senate can accomplish such recognition of his services. The bill recently introduced by Senator Hale was favorably reported from the Committee on Naval Affairs and promptly passed without discussion.

The bill authorizes the President to appoint Commander Peary a rear admiral with an extra number and places him on the retired list. An amendment was adopted giving him the pay of a rear admiral of the first grade.

The top notch pay of a rear admiral is $8,000 a year and that of the same officer on the retired list three-fourths of his active compensation. Thus Admiral Peary will receive $6,000 a year for the remainder of his life.

# Industrial Chimneys and Water Towers of Concrete Blocks

BY H. PRIME KIEFFER

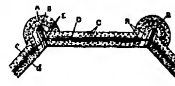
The employment of concrete blocks for the construction of factory or industrial chimneys and water towers is one of the most natural uses of that new form of building material. It is very surprising that the idea of utilizing separately molded blocks for this purpose should have come from Europe instead of America, where blocks have found a wider range of use than in any country in the world. The system is the ideal one for the rapid erection of factory chimneys. In the United States there have been in use some twenty different systems in which armored concrete is employed, but they all have some primary form of scaffolding in their designs. This is the underlying reason why these chimneys cannot be constructed more economically and rapidly. The method of constructing chimneys of separately molded concrete blocks is the invention of M. Dumas, an engineer and architect of Brussels, Belgium. It is controlled by Leon Monnoyer et Fils, also of Brussels, who furnished the data and photographs for the present article. The system is notable for its simplicity, its beauty of form, its economy in cost, and its adaptability to rapid construction.

The chimneys are like all others in that they are composed of three parts, the foundation, the base and the shaft. The shaft is formed of reinforced concrete of a special design. The form of the blocks is shown in the accompanying diagram. The number of blocks in each course always remains the same, yet there is a taper to the chimney. They are placed in regular horizontal courses to the required height, and upon the top is placed a special capping block of either concrete, cast iron or cut stone.

The builders work on a rough platform and from the interior of the structure, and each block is received by them ready for its particular position. Two men are usually employed above in laying the blocks, and two below to hoist them to the platform. The blocks in each succeeding course are placed in the opposite direction, that is to say, all the even courses will have the same direction and all the odd courses will take the reverse of this. In this manner, the joining of the blocks of one course, where they do not meet perfectly, will be covered by the blocks in the course above. As shown in the diagram, each block has at one of its extremities, a "hook" similar to the shape of the letter "U." This "hook" forms a hollow space which extends the full length of the chimney, and of course there will be just as many of these hollow spaces as there are sides to the chimney. Through these vertical hollow spaces are placed vertical iron rods B, varying in diameter according to the height of the structure. At each course these rods are tied or bound to the courses by U-shaped flat iron yokes *E*. These, in turn, are wired to a small iron rod D, which is placed between the courses horizontally and in a groove made for it in the top of the blocks.

The placing of the vertical rods in the openings and not in the substance of the shaft proper forms an important advantage of this system. The reinforcement is thus kept at a low temperature, and is not subject to the injurious effects which would arise from unequal expansion if the steel was in the center of the mass. Ferro-concrete is indestructible by fire so long as the temperature of decomposition of concrete is not reached, but it must be remembered that although the coefficients of expansion of cement are the same, the coefficients of conductibility are very different, and fracture is likely to arise if, from this cause, the temperature of the iron exceeds that of the concrete. Consideration of this condition is especially important in the case of a structure which is heated on one side only, such as a chimney.

A clever idea in connection with the design of the blocks is that there is need for only three, or at the most, four sizes of blocks for the average chimney of



A. Indicates the hidden reinforcing rods of the blocks.

**Cross section of a portion of a concrete water tower. Section at one end of the joining of two of the courses.**

150 feet high and with a taper of one to three per cent. This is made possible by the following arrangement. The molds by which the blocks are made consist of but three cast-iron plates, held together by wooden stop blocks, and three ordinary iron clamps. Different sizes of blocks can be made therefore, by simply changing the relative positions of the plates and the wooden stop blocks. After the blocks are molded, they are placed in the following manner. Take, for instance, the first row, at the base. Here, naturally, the blocks are of the largest size, and the arm of the block the longest. The arms of the blocks in this course are placed just to the edge of the hooks of the blocks, and in the next course the arms are placed just a little farther into the hooks, and thus each succeeding course has a diameter smaller than the one below it, and in this manner, the taper of the chimney is obtained. As the longest blocks are some three feet in length and the distance across the semicircular opening about six to eight inches, it is possible to make a considerable taper in this manner. For a taper of 1½ to 2 per cent, the size of the blocks is changed every forty or fifty feet. The blocks may, of course, be laid with absolutely no taper, and then one size, only, of blocks is used. Some chimneys have been constructed on this plan, but their appearance is not so graceful as those having a slight taper.

The concrete blocks are usually made at the chimney site, although they can of course be molded at a concrete block factory, and this may be economical in case there are several chimneys under construction in the same district. The proportions for the concrete mixture vary somewhat, but the usual mixture consists of about five parts gravel, three of sand, and two of cement. Dust of stone is used sometimes, and has given very good results. From an architectural point of view, the chimneys constructed with this system present a pleasing appearance. Being thinner than brick chimneys, they rise more gracefully from their bases, and yet the strength and stability which they actually possess is at once suggested to the eye by the appearance of strength which is presented by the protruding rounded angles.

A number of chimneys and water towers have been built in Europe after this system, and the two photographs presented in connection with this article show a water tower, and a combined water tower and chimney. The water tower, which is located in Uccle, a suburb of Brussels, Belgium, will be used in connection with the 1910 exposition to be held in that city. The tower and tank have a height of 145 feet and the latter has a capacity of 280,000 gallons. The structure is circular and is built entirely of concrete blocks and without molding of any kind excepting that used in the building of the concrete reinforcing struts surrounding the base of the tank proper. The inside of the tank is built up in practically six stories connected by a winding stairway. These different floors are divided into rooms which will all be occupied by engineers, foremen and other workmen during the exposition. The stairways are placed along the outer walls and the water remains in the center inclosed by a concrete covering of square cross section.

Concrete block chimney carrying two reservoirs of reinforced concrete.

Concrete-block water tower for the 1910 International Exposition at Brussels, Belgium.

INDUSTRIAL CHIMNEYS AND WATER TOWERS OF CONCRETE BLOCKS.

### Oil That Cold Will Not Affect.

It is often difficult to keep machinery properly oiled in cold weather, as the oil freezes in the oil holes and the cups, and the oil upon the ways of the lathe and planer becomes stiff, causing the machines to work hard. A good oil for winter use is made by mixing graphite with cylinder oil until in a thick or pasty consistency, and then adding kerosene until it flows freely. This oil will not become stiff at 14 degrees below zero, and is valuable to those operating machinery outside or in cold shops.—Power.

In his presidential address to the American Street and Interurban Railway Association, Mr. Shaw, at Denver, said that in round numbers there are 1,250 street and interurban railway companies in America, with a total of 35,000 miles of single-track and 75,000 passenger cars. The passenger carried annually is 10,000,000, and the gross income $44,000,000.

### THE CONSTRUCTION OF AN IMPROVED SILICON DETECTOR.

BY GEORGE F WORTS

The detector described here is one that can easily take the name 'improved,' being a radical departure from the coarsely-adjusted detectors generally used. If properly constructed and connected, it will easily pick up wireless messages sent from very distant points. The component parts are shown in Fig 1.

The base of the instrument is fashioned from hard rubber, 3 x 2 x ½ inches, ⅛ inch holes are bored in it one inch from either end. A support for the crystal cup is made from annealed brass, 4 inches in length, ¾ inch in width, and 3/16 inch in thickness. It is bent to an L shape, as can be seen in Fig 2.

The crystal cup is turned from brass rod ½ inch in diameter. It is threaded, as seen in Figs 1 and 2, to fit a thumb nut. The crystal is fastened in the cup by means of lead. This insures a good contact. The ad

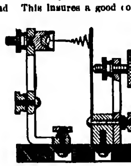

Fig. 1

SECTIONAL VIEW OF THE ASSEMBLED DETECTOR.

justing mechanism can be made to move a steel hair spiral, the point of which makes contact on the silicon to the thousandth part of an inch. The phosphor bronze strip upon which the spiral contact is fastened is 3 inches in length, ½ inch in width, of No 28 B & S gage sheet. It is bolted to a cube of brass which in turn is fastened by means of a machine screw to the base. This screw serves also as a binding post. The brass post supporting the adjusting screw is of 3/16 inch brass of the same stock as the L-shaped post. It is 2¼ inches in length, ⅝ inch in width, and 3/16 inch in thickness. A ⅛-inch hole is bored ½ inch from

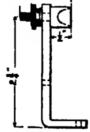

Fig 2

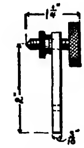

Fig 3

SUPPORTS FOR THE CRYSTAL AND THE ADJUSTING DEVICE.

one end to admit the machine screw that binds it to the brass cube. Another hole is bored ¼ inch from the other end and tapped to fit the adjusting screw. The adjusting screw has a large knurled rubber handle for adjusting purposes, also a lock nut to be tightened when the detector is at its most sensitive point.

This detector is comparatively easy to construct and is inexpensive. The one undesirable quality in silicon detectors—their ability to get out of adjustment—is almost entirely eliminated in this detector, due to the use of the spiral instead of the solid contact.

### INCREASING THE EFFICIENCY OF WIMSHURST ELECTRIC MACHINES.

BY GEORGE J MURDOCK

The Wimshurst static electric machine, as is well known, consists of two glass circles revolving on a compound axis in opposite directions. As usually made, this machine is inferior to the Toepler-Holtz type, although somewhat cheaper to make, and superior in simplicity. The latter quality has been without doubt one of the chief reasons why it is in general use wherever the small electric discharge this machine will give as commonly made, will answer the purpose.

In building both kinds of these interesting machines it is the practice to varnish the revolving glass circles with white shellac dissolved in alcohol. In the higher grade machines the best quality of shellac and grain alcohol are used for this varnish but for the toy variety wood alcohol and the cheapest grades of shellac are used. Some years ago the writer was building both Wimshurst and Toepler Holtz statics, but was unable to obtain a discharge from the Wimshurst type that could compare with the other kind, even when the glass circles were of the same diameter.

The development of the machines in both cases had extended over a series of years, and it was supposed the limit was reached. At this time the Toepler Holtz machines were giving with 26 inch circles sparks (using the Leyden jars) equal to the radius of the circles or 13 inches long, thick as the thumb and when discharging detonating like the sound of a rifle.

The Wimshurst machines with an equally large circle would not give sparks over 4 inches long, and about as thick as a knitting needle. Finally, in building a lot of six machines it was found some were much better than others. Strenuous efforts were made to ascertain what caused the increase in efficiency but without discovering anything different in the construction of those that showed the improvement from the others. In the next lot after this, however, all of the machines were capable of giving sparks 6 inches long, although the diameter of the glass circles was but 14 inches. The thickness of the spark had also increased to the size of a pipe stem and this wonderful increase of efficiency was attributed to some quality inherent in the glass of which the circles were made but inquiries made of the manufacturers of the glass failed to disclose any different methods of making the glass than had been followed for many years.

About this time the writer in varnishing some circles held one of them up to the light and was struck by its light green appearance and although giving it little attention at the time gained the impression that this change in color might have something to do with the increased efficiency still unaccounted for. Shortly after this a new lot of machines were built and every one of them had reverted to first principles so far as the spark was concerned, it being short, weak, and spindling. In the effort to find out what had caused the reversion the writer called to mind that just before varnishing the last lot a new brush had been used in a new batch of varnish.

It is customary in making the varnish to dissolve the shellac gum in a glass jar with a mouth just large enough to get the brush in conveniently and the brush is left in the jar between the construction of the different lots of machines. It was found that the old brush had been shedding its bristles, and to prevent this it had been bound around with some fine copper wire. The action of the varnish had been to corrode the copper and the salt had given the varnish the faint green color noticed some time before on the glass circles, although there had been nothing different in the color of the body of varnish in the jar apparent.

The suspicion dawned on the mind of the writer that this had been the cause of the increase of efficiency and the lack of it in the last lot of machines. Another batch of varnish was accordingly made, and in it was put about a quarter of a pound of fine bare copper wire. A new brush was procured and placed in the jar and the varnish allowed to stand in a warm dark room about a week, when it had assumed a light green color, and was used to coat the circles of a new machine.

This machine was found on trial to be even more efficient than the best of the others.

In experimenting with the newly discovered varnish it was found that if it was allowed to become a dark green the voltage of the machine was interfered with and while the spark would be thicker it would not jump as far. The best results were obtained when the color was a very light green. The reason for the increased efficiency was thought to be due to a decrease of the resistance of the shellac between the sectors on which the equalizing brushes bear.

This varnish was tried on Toepler-Holtz machines without their showing any marked increase perhaps due to their being already capable of delivering sparks equal to the radius of the glass circles.

The use of varnish made in this way will be found by amateurs and others to add greatly to the capabilities of the Wimshurst machine, and besides the light green color on the glass adds to the beauty of the instrument.

Many builders of Wimshurst machines as well as those experimentally inclined have trouble in making the brass sectors stick to the shellac. As tinfoil soon wears through from contact with the equalizer brushes, thin sheet brass is used by many on the better grades of machines to secure durability. Brass sectors can be made to stick permanently in the following manner.

In varnishing the circles about three coats is generally applied with a large flat camel's hair brush. Each coat is allowed to become moderately hard before applying the next. After the last coat is applied, and has stood about fifteen minutes mark the locations where the sectors are to go (they should be evenly spaced), and after applying some varnish to the under side of the sector, press it down into the soft varnish until a slight ring swells up around the margin of the sector. After the varnish is hard an examination will show the sector dovetailed into the varnish from which it will never separate as it will if cemented in any other way on account of the expansion and contractions of the brass being so much greater than the glass, and causing the sector to become loose.

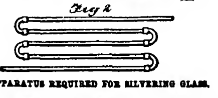
### SILVERING GLASS AT HOME.

BY A J JARMAN

A good glass mirror made with one's own hands is a thing to be proud of. Mirrors are now seldom made by the tinfoil and mercury process because of the dangerous character of the work, but pure silver is used instead. The silver process is not in the least dangerous to the workman. The formula here given is one that has been in use in several looking glass and art mirror factories in the city of London. The

Fig 1.

Fig 2



APPARATUS REQUIRED FOR SILVERING GLASS.

chemicals used must be of absolute purity (chemically pure) and all operations in preparing the glass must be carried out with care and scrupulous cleanliness. The surface to be silvered must not be pressed upon by the fingers or thumbs they would leave an indelible impression.

The first thing to be done is to make a small table out of a piece of slate about ¾ or ½ inch thick, 10 or 12 inches wide and 18 inches long. These measurements are not binding, any piece of slate about the above size will do. A wooden trough must be made with grooves at the top edges for the slate slab to rest in. There must be a space of 2 inches between the slate slab to the wooden bottom as indicated in Fig 1. In this space is a coil of pipe arranged as shown in Fig 2. The pipe is of about ¾ inch bore and through it steam is passed to raise the temperature of the slate slab to about 120 deg F. In fact just hot enough for the hand to bear. The steam can be supplied from an ordinary tea kettle placed near the depositing table with a rubber tube connecting the coil to the spout of the kettle. Uniform heating of the slate slab is essential. The coil can be easily made of ½ inch iron gas piping screwed into U-shaped cast iron connectors, as shown in Fig 2. The slate slab can be covered with black oilcloth and made perfectly level. The following stock solutions must be made up and carefully filtered through absorbent cotton ready for use.

Stock Solution A.—Nitrate of silver 3 ounces, distilled water 10 ounces, strong water ammonia 1¾ ounces. This solution must be stirred well and allowed to stand five or six hours, then add 10 ounces more of distilled water and filter.

Stock Solution B.—Rochelle salts 4 ounces, distilled water 20 ounces.

Stock Solution C.—Distilled water 40 ounces, protochloride of tin 5 grains.

Clean the glass plate or plates with very fine rouge and water taking care that no trace of grease whatsoever comes into contact with the glass or the cloths or chamois leather used for polishing. When cleaned the plate must be flooded all over with the tin solution. Pour this solution off and wash the plate well with distilled water. Lay the plate wet side up upon the table with four clean wood wedges at each corner. Let the glass rest on the wedges so as to allow a slight adjustment if required for leveling. The mixture for silvering is made up as follows:

Distilled water 20 ounces, stock solution B 1 drachm by measure, stock solution A 1 ounce by measure. The glass plate being quite level and still wet pour this mixture carefully and slowly upon the center. It will flow evenly all over until it stands about one-eighth of an inch deep all over the plate. Any tendency to run to one end must be rectified by the wedges. The plate now being completely covered with the silvering mixture must be left to itself for about two hours, the heat being kept up during this time and when it is found that the whole of the silver has been deposited the liquid must be poured off by tilting and allowed to run into a stoneware crock and saved

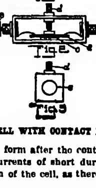
for the waste silver it contains. If it is desired to increase the thickness of the deposit of silver, the operation must be repeated as soon as the silvering is complete, wash the plate well in a soft stream of running water, stand it cornerwise to drain and dry. When dry the following protective varnish must be used as a coating to protect the deposited silver: Shellac, ½ pound, wood alcohol, 6 pints. As soon as this coating has dried it must be painted over again with the following paint: Red lead ¼ pound, white lead, ½ pound, mixed with enough boiled oil and a small quantity of turpentine to make a good covering with a single coating. A small quantity of gold size must also be added to insure quick drying and a tough adhering quality. The mirror is now ready for framing. If much work has to be done, it will be advisable to cover the slate all over with a piece of felt, and keep the felt wet during the operation for two reasons. First, no pieces of woollen fiber can settle upon the plate, and secondly, the heat from the slate slab is communicated to the glass better than from a dry surface.

For a regular workshop a very good size is 4 by 7 feet, with a gutter cut around the slab, so that the spent silvering liquid can run from the tilted plate, around the table and be collected by running through a hole at one corner. In this case the liquid will be sure to come in contact with the felt. This will prove of no consequence, because in time it will become saturated with silver, which will realize twenty times its first cost when sent to the silver refiner, and not only pay for a new felt covering, but increase the size of the pocket book at the same time. The quantity of nitrate of silver required to coat a square foot of glass with a moderate coating of silver is 18 grains. An estimate as to cost can be made from this amount.

## SELENIUM CELL WITH CONTACT BY PRESSURE

BY W. S. GRIPENBERG

The usual method of making a selenium cell consists in pressing the electrodes against a piece of crystallized selenium, which decreases its resistance to an electric current, when submitted to the action of light. The quality of selenium can be perfectly controlled, as it needs not come in contact with metal when fluid in which state it dissolves nearly all metals (i. e., the electrodes). This is of importance, because small quantities of other elements sometimes have considerable influence on its sensitiveness. Moreover a piece of selenium, that for some reason has lost its efficiency, can be easily replaced by another piece, at low cost. The most important point, however, is that the contraction or decrease in volume (5 to 8 per cent), which is inseparable from the process of crystallization, has no influence whatever upon the contact with the electrodes, as the piece of selenium is



SELENIUM CELL WITH CONTACT BY PRESSURE.

given its definite form after the contraction has taken place. Strong currents of short duration do not lead to the destruction of the cell, as there is full scope for expansion.

Despite these important facts, this method has not been hitherto used, because very thin plates of selenium are necessary, as the action of light is limited to an extremely thin layer of the exposed surface (calculated by Marc to be about 1/500,000 inch thick). Moreover, selenium is rather fragile and being of high resistance, heavy pressure must be used in order to realize good contact.

The author discovered that selenium, when molten between a cold and a very hot glass plate, strongly adheres to the latter, after the crystallization. It is thus possible to cover a thin (1/250 inch) flexible glass plate with an exceedingly thin coating of selenium (1/1 000 to 1/30 000 inch) which has a highly polished surface that gives very good contact with the electrodes. These consist of gilt stripes on a glass plate (Fig. 1). There are from 250 to 2,500 electrodes on every inch.

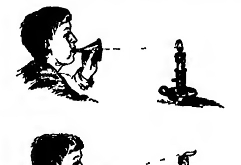
Cells constructed after this method are very reliable and show remarkable constancy. They are of small specific working surface. The following is a description of a cell actually made:

Working surface = ¼ by ¼ inch.
Resistance in the dark = 20,000 ohms.
Resistance in ordinary daylight = 10,000 ohms.
Resistance in strong light = 3,000 ohms.
Maximum intensity of current = 0.0016 ampere.
Fig. 2 gives a diagram of the cell.
Fig. 3 is an end view of same.

Glass plates with a thin coating of metal (silver) have before now been used as electrodes for substances sensitive to light. This combination or at least the results attained are new.

## SOME SCIENTIFIC AMUSEMENTS.

*The Candle and the Funnel.*—Ask a person to extinguish a lighted candle, two feet distant from his mouth, by blowing through a common tin funnel with his lips applied to the stem. Almost invariably, he will fail to accomplish the feat, although he could easily have blown out the candle without using the funnel. Now put your own mouth to the stem of the funnel and blow out the candle. If you have any skill in performing tricks you can repeat this one many times without betraying its secret to the average spectator. The secret is this: When you blow into the small end of a funnel, your breath follows the inner surface of the cone, and not only shuns the axis, but produces eddies of such a character that there is actually a slight back draft or inward current at the center of the wide mouth of the funnel. You, therefore, hold the



RIGHT AND WRONG WAY OF BLOWING OUT A CANDLE.

funnel so that some part of its conical surface would, if extended, strike the candle flame. An inexperienced person naturally directs the axis of the funnel toward the candle and consequently fails to extinguish the flame. If he stands quite near the candle and blows gently the flame will even be drawn toward the funnel by the inward current. The whirling motion of the air may be made visible by using a glass funnel and filling it with tobacco smoke.

*Paradoxes of Ebullition.*—Everybody knows that water boils at the temperature of 212 deg. Fahr. But if an uncorked bottle partly filled with water is set in a saucepan containing water in which a good deal of salt has been dissolved, and the pan is heated over a spirit lamp or otherwise, the water in the bottle will begin to boil while the water outside still remains perfectly quiet. Yet the water outside must be at least as hot as the water inside (212 deg. Fahr.), for the latter is heated by the former. Hence we see that water which contains salt in solution does not boil at 212 deg. Fahr. The same effect is produced by dissolving any other solid substance in the water.

Now, if the bottle is taken from the hot brine and corked, the water in the bottle stops boiling, but it will boil again, even after it has cooled many degrees, if cold water is poured on the upper part of the bottle. The explanation is that the boiling point of water is affected by pressure. It is about 212 deg. Fahr. under the ordinary pressure of the atmosphere (exactly 212 deg. when the barometer stands at 30 inches) but if the pressure is reduced, water boils at a lower temperature. When the water bottle was corked and taken from the fire, its upper part was filled with steam at atmospheric pressure, which had expelled the air originally present. As the bottle cooled, this steam partly condensed and its pressure was diminished, but not sufficiently to permit the water to boil, because the water cooled also and its gradually diminishing temperature was always a little below the boiling point corresponding to the actual pressure. But the application of the cold water caused a rapid condensation of steam and a sudden lowering of the pressure without having much cooling effect on the water, which consequently began to boil.

*Distillation.*—The same apparatus may be employed to illustrate the process of distillation. The brine in the pan is replaced by fresh water, a hole is bored in the cork and a glass tube is fitted to the hole. To the water in the bottle is added one-tenth its volume of alcohol, or less. The bottle and pan are placed over the lamp, as before, and heated gently. Before the water in the pan has reached the boiling point the vapor of the more volatile alcohol (mixed with a little water vapor) issues from the end of the glass tube, where its presence can be detected by its odor or by the application of a lighted match, which will result in the production of a tall blue flame. The jet should not be lighted until the mixture has been heated long enough to expel the air from the bottle, as the ignition of a mixture of air and alcohol would produce a violent explosion. For this reason the cork, though it should be air-tight, should not be inserted too tightly. With this precaution an explosion will drive out the cork, instead of shattering the bottle. This experiment, and the others performed with this apparatus, should not be attempted by children or careless persons.

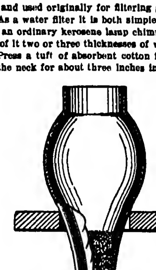
*Hero's Fountain.*—If the jet of flame issuing from the tube is extinguished and the tube pushed down until it dips into the water, a fine liquid stream will

MODIFIED FORM OF HERO'S FOUNTAIN.

be thrown high in the air by the pressure of the mixed vapors of alcohol and water in the upper part of the bottle.—Kosmos.

## A SIMPLE EFFECTIVE FILTER.

The filter here described was first made by the writer in 1878, and used originally for filtering gelatine emulsions. As a water filter it is both simple and effective. Procure an ordinary kerosene lamp chimney. Fit over the end of it two or three thicknesses of washed cheese cloth. Press a tuft of absorbent cotton into the small part of the neck for about three inches in depth, insert



HOME-MADE FILTER.

the chimney, and place it in a hole cut in a wooden shelf as a support. Pour the water in until the filter is filled, when it will be observed that any organic matter, chips of iron rust, etc., will be retained by the cotton. The fine organic matter may penetrate the cotton for about one inch, but no farther. The resultant filtered water will be bright, clean, and pure.

A paper dealing with "Research on Metallic Filament Lamps," by Mr. F. H. Reakes Lavender, was recently presented at a meeting of the Birmingham Institution of Electrical Engineers. The research was undertaken in order to investigate the conditions of working as regards voltage, and efficiency and percentage drop in candle-power, giving the most economical life in the case of metallic filament glow lamps, and to determine as far as possible the cost of illumination with this source of light. The author stated that the useful life of a lamp, and the drop in candle-power which it was advisable to allow for a given voltage, depended on the cost of current and the price of the lamp. The cheaper the current, the longer the life, and the greater the admissible drop. Taking the current at 5d. per unit as an average price, and the lamp run at rated voltage, then it paid in the case of the tantalum class of lamp to throw it away as soon as the candle-power had fallen to 3 per cent below its original value. This result appeared startling at first, considering the large initial cost of the lamp. However, by the time that point was reached the lamp had been burning for 1,500 hours at the best possible efficiency, so that the cost of the lamp per candle-power had become small.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

ARTIFICIAL AIGRET AND LIKE ARTICLE.—M. Veit, New York, N Y The aim in this case is to provide an artificial ornament, such as an aigret, plume, feather, hat and dress trimming, military ornament, hair ornament and the like, and formed from a sheet of celluloid or other material, and arranged to provide graceful filaments projecting integrally from a self-sustaining core.

BODY BRACE.—R. F MacClemmy, New York, N Y This invention relates more particularly to a shoulder brace, in which there are two back sections, each having an arm hole therein, lacing or cords connecting the sections together, and belt sections connected to the ends of the cords and buckling together in front to adjust the back sections in respect to each other Mr MacClemmy has invented another body-brace, and one of its main features resides in the construction of the upper ends of the stays, so that one of the stays is secured across its top and the other is left partially free, so that it may overlap the first-named stay, and the intermediate portion will be folded to a definite and predetermined position

### Of Interest to Farmers.

CONCAVE FOR THRESHING MACHINES.—W L. Hay, Franklin, Tenn This improvement is for use for threshers of all kinds. It provides a concave having adjustable sections so that one of the sections may be shifted to disengage the teeth without disturbing the relative position of the teeth immediately adjacent Simple means are provided for effecting the adjustment.

HARROW.—A M Hauck, Seattle, Wash This invention relates to harrows provided with wheels for cutting or pulverizing the soil or clods The invention provides means whereby the shafts upon which the wheels are mounted may be moved toward and from one another, in order to vary the degree of fineness with which the earth is pulverized.

### Of General Interest.

BATTLESHIP ARMOR.—E. P Watson, Sr., Bentonville, Ark The armor is such as carried by battleships, protected cruisers, and other warships. Merchant ships can be constructed near the water line in accordance with the present improvement, but the shell resisting parts of the armor may be omitted during peace, but applied to the ships so as to transform them into armored ships of war

PROCESS OF WIRING BOTTLES.—O Tosse, Bisagmadsgade 16a, Copenhagen, Denmark. The invention is especially adapted to prevent the twisted sharp edges of wire from sticking out and thereby constituting a common source of danger from cuts and wounds to those who later on have to handle the bottles. The process can be carried out by hand or with a pair of pliers.

LIQUID-COOLER.—H Russell, New York, N Y An object of the inventor is to provide a cooler in which ice or other refrigerating substance is contained in a vacuum and is surrounded by vacuum chambers to minimize the melting of the refrigerating substance, owing to the transmission chamber, and which has means for conducting the fluid to be cooled through the refrigerating chamber

SCREEN FOR IRRIGATING DITCHES.—T A Powers, Slack Wyo This invention is an improvement in screens for ditches, especially for irrigating ditches to be placed at or near head gates. In operation the screen will stand normally when the gate is in position for use at an angle of about forty five degrees, hinged at its lower end and adapted at its upper end to be depressed down stream by the action of pressure from above and to permit the debris to pass after which the screen may be readjusted to position for use

DISPLAY RACK.—J A. Bogar, Lykens, Pa. This invention relates more particularly to such racks as are provided with frames, on which rugs, wallpaper or the like can be suitably arranged for display purposes, and which are further provided with means whereby any number of objects on display can be temporarily removed from the frames to disclose a desired one originally concealed by the same on account of their super-position

FOLDABLE TABLE AND ATTACHMENT THEREFOR.—H F Thomas, Natrona, Pa. This invention refers to an improvement in foldable legs for tables and in a pedal attachment for such legs. It is particularly designed for use with tables, or like supports, for portable foldable dark rooms used for photographic purposes, but it is not restricted to such use.

### Hardware and Tools.

COMBINATION PADLOCK.—L. Rosen, Union Hill, N J In this case a locking mechanism is controlled by a combination mechanism. The device is intended to be strong in construction, inexpensive and of a type that cannot be readily picked. Simple means provide for a series of combinations that may be changed almost indefinitely

LOCK.—J Jonkune, Pocatello, Idaho. In the arrangement of this combination padlock the combination may be easily changed, and should any one attempt to discover the combination by bringing the recesses into register, with the bar withdrawn, such attempt would be thwarted, since the combination would not answer after the disk was returned to its first position.

### Machines and Mechanical Devices.

AUTOMATIC ADJUSTABLE REEL.—C H. Coon, Saugerties, N Y The aim of the inventor is to produce a reel in which the virtual diameter remains sufficiently constant In other words, the diameter of the reel reduces itself automatically as the web of the material wraps upon it In this way the length of material wrapped upon the reel in one revolution remains constant, and when the material on the full reel is cut, the sheets will all have the same length

COUNTERBALANCE FOR WATER PUMPS.—W Kortus, Jr Brinkman Ridge Wis. The purpose of this invention is to provide a construction for a counterbalance that is an attachment for a water pump which will balance the weight of the pump rod and the bucket on it, and of water lifted by the rod and bucket on it and of water lifted by the rod and bucket, thus reducing labor in operating a pump having the improvement

STEAM RENDERING TANK AND PRESS.—C H Stalker, New York N Y The objects here are, first, to provide a tank for cooking materials out of which grease oils etc, are rendered under steam pressure second to draw off the grease oils etc after the materials have been cooked third to drain the water and remaining grease from the materials left in the tank fourth, to press the materials for the removal of any still remaining oil grease, water, etc

### Prime Movers and Their Accessories.

ROTARY ENGINE.—W G Sheppard, Indianola, Neb The device consists generally speaking of a rotor having a vane fixed thereon, a fulcrum valve means for letting a motive fluid in between said fulcrum valve and said vane on either side thereof, and means for exhausting the motive fluid from between the fulcrum valve and the vane

INTERNAL COMBUSTION ENGINE.—F Reaugh Oak Cliff Texas. The invention resides in a peculiar arrangement of a plurality of cylinders in conjunction with a single main or engine shaft with which shaft one or all of the cylinders may be connected independently and at will, thus enabling the main shaft to be driven from the operation of a single cylinder while the other cylinder or cylinders, with all of their immediately allied parts, remain absolutely inactive

### Railways and Their Accessories.

RAILROAD-TIE.—J S Miller, Clinton, Neb Mr Miller's invention has for its purpose the provision of a concrete tie on which the rails may be supported the tie being so constructed that it is reinforced by the means provided for securing the rails Also the provision of means in connection with the reinforcing members for spacing the ties apart at a predetermined distance from each other

### Pertaining to Recreation.

BOWLING-CABINET.—R H Mulford, Connellsville, Pa This cabinet is especially adapted to be used as part of the furniture of a bowling alley The object is to produce a cabinet which will constitute a bench upon which the players or spectators may seat themselves, and which has a special construction enabling the cabinet to hold the bowling pins, the bowling balls, and also the hats and coats of the players.

PYROTECHNICAL BUTTON.—A. Jeder, New York N Y A special object of this invention is to provide a trick or joke device, which may be secured on the person, and which when ignited, produces a startling or unexpected effect Means provide for safely and securely holding the compound, so that it may be worn and ignited, while on the person without liability of personal injury

GAME APPARATUS.—C F Dorr, Yonkers, N Y The invention pertains to parlor games, and its aim is to provide an improved game apparatus, more especially designed for playing baseball, and arranged to afford amusement to the players and onlookers and to require considerable skill on the part of players to successfully play the game

MUTOSCOPE.—A S. Ferguson, Springfield Mo. The invention is adapted for use as a toy or parlor amusement, the same consisting essentially of a series of photos or other pictures arranged radially in a circle, thus forming what may be termed a picture wheel which being rotated, the pictures are successively turned back and thus exhibited to the onlooker

### Pertaining to Vehicles.

GASOLENE FEED.—A W Rohacker Bottineau, N D The object here is to provide a means for insuring a constant supply of liquid fluid to the carbureter of a power driven vehicle regardless of the inclination of the body of the same as when hill climbing In vehicles having the engine in front, and the fuel tank beneath the seat, the carbureter will not get a sufficient supply of fuel when the front of the vehicle is elevated, as in hill climbing, especially if the fuel supply is low

Note.—Copies of any of these patents will be furnished by Munn & Co for ten cents each Please state the name of the patentee, title of the invention, and date of this paper

## NEW BOOKS, ETC.

Manual of Physical Geography. By Frederick Valentine Emerson, Ph.D New York The Macmillan Company, 1909 8vo, 291 pp Price, $1 40

The exercises in this manual have for the most part emanated from the author's classroom experiences There is presented a variety of exercises, some of them advanced in character that will cover topics capable of laboratory illustration usually presented in a course in physical geography Some of the questions are practical For instance, let us take up the subject of fog Here are a few of the questions What is fog? What is its general cause? Where have you seen it occur? If over land or water, what is the apparent cause? How dense is it? Does it disappear suddenly or slowly? Did you see the fog around a piece of ice or a water pitcher on a hot day? What effect has fog on bodily sensations? What on commerce? The fogs of London The book is especially valuable to advanced students

Practical Engineer Pocket Book for 1910 London The Technical Publishing Company, Ltd 16mo, 684 pp. Cloth, price 1s net, leather, gilt, with diary or ruled section paper, 1s. 6d net, postage 3d extra. Price, 60 cents.

We have reviewed various editions of this book for a number of years and have found that the information conveyed was reliable and is presented in such form as to be very readily available The excellent indexes are to be particularly commended

Ether of Space. By Sir Oliver Lodge, F R S 16mo, 168 pp

Sir Oliver Lodge needs no introduction to the readers of this paper He is well known as an exponent of the ultra modern physical theory with which the English school of physicists have been identified In this book he explains in a simple way the necessary conception of an ether and formulates theories which, although some of them have not yet gained current acceptance will undoubtedly do so in time

The Water Supply, Sewerage, and Plumbing of Modern City Buildings By William Paul Gerhard, C E. New York John Wiley & Sons. London Chapman & Hall, Ltd, 1910 8vo, 493 pp Price, $4

The present work is an extremely valuable one The engineering problems connected with the modern city building are very complicated The chapters, while correlated to each other, are purposely so written that each one is complete in itself and each one may be read or studied without reference to the others The book is splendidly illustrated by means of helpful diagrams and half tones. The titles of the chapters are as follows Essential Features of the Hydraulic and Sanitary Engineering of Buildings Sanitary Fixtures and Appliances. Advanced and Simplified Plumbing Plumbing in its Relation to Disease and Municipal Control of Plumbing Domestic Water Supply The Water Supply of Large Modern City Buildings. The Maintenance of Pipe Systems for Sewage, Gas and Water Rules on Plumbing Water Supply and Sewerage chiefly for Hospital Buildings and other Public Institutions. Mr Gerhard has an international reputation as a sanitary engineer and this book may be looked upon as authoritative

Automobile Driving Self-Taught By Thomas H Russell, M E, LL.B Chicago The Charles C Thompson Company, 1908 12mo, 222 pp Price, $1.

As comfort and safety in automobiling depend to a very large extent upon the skill of the driver it should be the aim of every one who intends to drive a car to acquire a knowledge of the approved methods of driving It is the object of this book to present such information in a convenient practical manner so as to make it comparatively easy for any motorist to acquire skill in the management and care of his machine Study and practice combined will surely develop the experience which is needed nowadays at the wheel being demanded alike by the interests of the automobilist and of the non motoring public The careless or ignorant driver is a menace not only to the safety of the public, but also to that of his passengers The daily experience of every motorist demonstrates the need of carefulness in driving and there is no longer any excuse for ignorance The methods of driving are described in this work and those which have been found best in actual experience on the road. From these pages the motorist can learn how to start, drive and manage his car under all conceivable circumstances Those methods of caring for the car when not in use are also plainly shown as well as the manner in which a car should be laid up when necessary The book appears to be a most practical one

Concrete. By John C Trautwine, Jr and John C Trautwine, Third, Civil Engineers. New York John Wiley & Sons, 1909 16mo Price, $2 net

Trautwine's Civil Engineer's Pocketbook is too well known to need any praise at our hands The nineteenth edition of 1909 completed the hundredth thousandth copy which is a phenomenal sale for a scientific and technical book. In fact, we believe this is the largest sale on record for any such book The most notable of the new features in this new edition is a series of articles on concrete plain reinforced, natural cement, sand and water Practically all this matter, occupying about 200 pages, is entirely new as far as its publication is concerned. For the convenience of many engineers the section on concrete has been reprinted in the form of a handy volume which should be in the hands of all engineers Typographically, the book is perfect for an engineer's pocketbook The high professional standing of the engineers who have compiled the book is sufficient guarantee of its accuracy

Radford's Combined House and Barn Plan Book Edited by William A Radford New York and Chicago The Radford Architectural Company, 1908 4to, 287 pp Price, $1

The volume before us is a most practical one, giving designs for barns, livery stables, grain barns dairies, cow barns feed lofts cattle sheds, poultry houses implement sheds vehicle sheds, hog houses, corn cribs smoke houses, granaries, tank houses, etc The illustrations serve the purpose, although they are rather coarse Prices for blue prints, which would enable any one to build these barns, are listed

Practical Engineer Electrical Pocket Book and Diary for 1910 London Technical Publishing Company, Ltd 16mo, 570 pp Price, cloth, 1s net, leather, gilt, 1s 6d net, postage 2d extra.

This welcome annual visitor contains as usual valuable statistics, data, rules, tables, formulas etc, and should be in the hands of all who are interested in electrical matters

Problems in Wood Turning By Fred D Crawshaw, B S, M E. Peoria, Ill The Manual Arts Press, 1909 12mo Price, 80 cents.

Wood turning is considerable of an art, requiring quite a little knack of handling the tools. The present work is an extremely practical one, and the illustrations are the best we have ever seen in a book on wood turning The various projects are admirably worked out

Handbuch für Heer und Flotte. Enzyklopädie der Kriegswissenschaften und verwandter Gebiete, herausgegeben von Georg von Alten, Generalleutnant z D, unter Mitwirkung von mehr als 200 der bedeutendsten Fachautoritäten Complete in 108 instalments. Price per instalment, 50 cents Berlin, Leipzig, Vienna and Stuttgart Deutsches Verlagshaus Bong & Co.

The first three instalments of the second volume of this remarkable military and naval encyclopedia lie before us. The instalments extend from "Bayreuth" to "Beurkundung" In the care which has been taken in the individual articles these new instalments are well up to the standard of those which we have previously reviewed Of particular interest are the articles on benzine and benzol The essay on Belgium may well be regarded as a model of good military writing for it discusses clearly and masterfully the military geography history and military system of a small but important European body politic

Power, Heating and Ventilation A Treatise for Designing and Constructing Engineers, Architects and Students By Charles L. Hubbard, B S, M E. Part II, Power and Lighting First edition Brattleboro, Vt The Technical Press, 1909 8vo pp 397 Price, $2

The author has produced a thoroughly practical book which will be warmly welcomed by all engineers who have charge of power and lighting plants There is always room for a good book on this subject and the author has certainly produced a most admirable treatise which is worthy of a large sale

Power Heating and Ventilation A Treatise for Designing and Constructing Engineers Architects and Students. By Charles L. Hubbard, B S, M E Part III Heating and Ventilation First edition Brattleboro, Vt. The Technical Press, 1909 8vo, pp 647 Price, $2

This is a very practical book dealing with all phases of warming and ventilation Even such subjects as electrical heating are taken up The illustrations are excellent the expensive but eminently successful wax process being used The tables are also of great value The subject is treated with care discrimination and the book cannot help but be of great use to all engineers

Romantic Germany By Robert Haven Schauffler New York The Century Company, 1909 397 pp Price, $3 50 net

The beautiful book with a charming cover so suggestive of old Germany is a delightful one The plates are charming and they are beautifully reproduced in various tints and colors The cities which are discussed are Danzig Berlin Potsdam Brunswick Goslar Hildesheim Leipzig Meissen Dresden Munich, Augsburg and Rothenburg—certainly a galaxy of names to conjure with It has been a long time since a good book has been produced on Germany which

deals with the land itself and not with its politics, history, sociology, commerce and science. Indeed the world's visitor has to look back to "Views Afoot," written by young Bayard Taylor in the year 1846. To those who have left the beaten track Germany still remains the land of the Nibelungenlied and of Grimm's Fairy Tales, of gnomes and giants, storks and turreted ringwalls, of Gothic houses in towns and the glamour of medieval courtyards. Many of these towns have preserved almost intact their old-world magic and a touch of real romance is to be found as well as beauty in every one of the larger cities, and it is of these which we have been taught to consider typical of its present. It is hoped that the present volume will lure the traveler from his hard beaten track in France, Switzerland and Italy to the fresh regions of Romantic Germany.

SIMPLIFIED MECHANICAL PERSPECTIVE. By Frank Forrest Frederick. Peoria, Ill.: The Manual Arts Press, 1908-1909. 8vo., 54 pp. Price, 75 cents.

This is a treatise for the use of high schools, technical and manual training high schools, evening and industrial schools and art schools. The author has used the methods outlined for more than twenty years, and he states that he has never had a student learn much about the subject unless he carefully worked each problem and thoroughly understood it before attempting the next. The problems are admirable and a thorough mastering of this work will give any one an excellent idea of perspective.

THE DESIGN AND EQUIPMENT OF SMALL CHEMICAL LABORATORIES. By Richard K. Meade, B.S. Chicago: The Chemical Engineer Publishing Company, 1908. 12mo., 136 pp. Price, $2.

It very often happens that the young chemist, perhaps fresh from college, is called upon to design and equip a laboratory when his knowledge of how it is to be done is rather meager. The experienced chemist confronted with the task can usually bring to bear upon the subject sufficient practical knowledge gained from other laboratories in which he has worked to arrange and equip a laboratory which will meet fully his requirements and can do so in many instances better than any body else can do it for him. Many things which are done in the college laboratory are impossible in the private laboratory where means are limited; for instance, ventilation of the hoods, gas supply may be non-existent, etc. In these young chemists the suggestions in this book on the design and equipment of small laboratories are made. But even experienced chemists may gain valuable points from it. There is an extremely small amount of literature on this subject, so that a thoroughly practical book like this should be warmly welcomed.

NUTRITION AND DIETETICS. By Winfield S. Hall, Ph.D., M.D. New York and London: D. Appleton & Co., 1910. 8vo., 315 pp.

This is a valuable manual for students of medicine, for trained nurses and for dietetists in hospitals and other institutions. During more than ten years the author has been presenting the subject of nutrition to classes of undergraduates in medicine and to the nurses of two of the large city hospitals. There has been a repeated request for a concise text book suitable not only for undergraduates and nurses but also for the general practitioner and covering the whole field of dietetics, but no such book seemed available. The one thing which is notable in this volume is the absence of receipts. These are hardly necessary as the doctor does not require them and the nurses already have them in other forms. The book is a very excellent one, including a classification of diets. The book is printed in a good size type and is well bound.

MODERN LETTERING, ARTISTIC AND PRACTICAL. By William Heyny. New York: William T. Comstock, 1909. 8vo., 116 pp. Price, $2.

This is a book of instruction primarily valuable in the hands of the beginner and of assistance to the experienced workman. Modern Lettering essays the subject from the practical standpoint from cover to cover. The author, a man of experience and of artistic temperament, boldly sets forth his ideas and propounds his methods in concise language. Directions even to minute details are given, all of which are valuable to the student. The plates are all on a large scale and the letters are clear and sharp. The French Roman is a new letter in this country and will be appreciated for its refinement, beauty and legibility. Much valuable information, the fruit of the author's long experience, is given on the choice of alphabets, the arrangement of words and the spacing of letters, with good criticism of faults of modern lettering.

IN A YORKSHIRE GARDEN. By Reginald Farrer. London: Edward Arnold, 1909. 8vo., 110 pp.

The author is very much in love with his subject. He has already written "My Rock Garden," "Alpine and Bog Plants," as well as other works. The present volume deals with "The Dreadful Dawn."

NATURAL SALVATION (SALVATION BY SCIENCE). By Charles Asbury Stephens, M.D. Norway Lake, Me.: The Laboratory, 1910. 8vo., 157 pp.

# INDEX OF INVENTIONS

**For which Letters Patent of the United States were Issued for the Week Ending February 8, 1910,**

**AND EACH BEARING THAT DATE**

[See note at end of list about copies of these patents.]

**OTHER WORLDS IN SPACE.**

*(Continued from page 160.)*

graph is being taken. A careful observer with such an accurate instrument will obtain the spectrum of the star in the middle of the photograph flanked on either side by the spectrum of the metal iron or titanium or the gas hydrogen, placed there by the use of the electric current and induction coil. Astronomers use different metals for the purpose of comparison, the Yerkes Observatory, for instance, employs both iron and titanium on the same plate.

A good photographic spectrum will then consist of that of the star to be investigated, supplemented by the lines of the comparison spectrum. How are these spectrograms to be interpreted? And how can they tell us anything about stellar motions? Remembering that light is a wave motion, we have a simple analogy in the case of sound, and one with which everyone is familiar. In traveling in an express train which passes another going in the opposite direction, we have all of us noticed that the pitch or tone of the whistle or bell of the other engine suddenly drops as it passes by us. The reason is that sound is also a wave motion (though the waves are much different from those which cause light) and the quickly approaching engine causes more waves to crowd into our ears each second of time than it does when the engines are not moving. As the tone is determined by the number of waves which fall on the ear drum every second, the consequence is that the pitch of the whistle or bell is raised while the two trains are approaching, and for the same reason it is lowered when the two after passing are going away from each other. The change in the tone of the whistle depends on the speed of the two trains and also on the velocity of sound, and as these are comparable, a divided change in tone is readily noticed.

Applying the same ideas to light we have what is known in science as the Doppler principle of motion in the line of sight. A vast number of waves of light impinge on the retina of the eye in every second and excite in the rods and cores the sensation which our brain interprets as light. If the light is red, then four hundred millions of millions of waves ($4 \times 10^{14}$) enter the eye every second; if the light produced is violet, about twice that number. In spite of the fact that these vast numbers of waves come into the eye so quickly, if the source of light toward which we are looking is moving toward us, then as a result more waves are crowded into the eye in each second, and if the body is moving away from us fewer than the normal amount come into the eye. Evidently the shift from the normal is excessively small, but even so, it is a measurable quantity for the astronomer with his methods of precision. A shift toward the violet means that the waves are crowded together and the star is approaching the earth, a shift toward the rear end of the spectrum signifies that star and earth are separating from each other. A measure of the shift gives the velocity of the star in miles per second.

The calculation of these velocities in the line of sight is now a great, fruitful field of astronomical research and many important developments have been made in it. It is a far cry from the small spectroscope that is ordinarily used in a physical laboratory to the magnificent Yerkes telescope and its refined spectrograph (SCIENTIFIC AMERICAN, December 25th, 1909). This required not only vast improvements in the instruments themselves but in methods all through as well. The refinements of present day work are due more to Prof. W. W. Campbell, director of the Lick Observatory, than to any other man. He has been a leader in all plans of spectroscopic work, and his methods are largely followed wherever such researches are attempted.

To the uninitiated the photograph of a stellar spectrum shows remarkably little. Even with the great 40-inch Yerkes

long a photographic plate 1 2/3 x 4 inches only is used and in the center of this are some faint streaks of light about two inches long and possibly one sixteenth of an inch in width This tells the whole story of the star's motion Naturally this photograph is placed under the microscope for examination and there it appears magnified and is measured The physical constitution of the star the metals that compose it is known from the lines of the stellar spectrum hydrogen for instance showing its badge by a series of prominent lines The motion of the star is shown by the placing of these lines, whether they are shifted from their normal position as given by the comparison spectrum to the violet or toward the red end of the spectrum If there is hydrogen in the star then the lines of the hydrogen comparison spectrum give the position of rest or zero velocity with respect to the earth, and the amount of the shift measured under the microscope gives the motion of the star If there are other lines in the spectrum of the star (as is usually the case) we can readily in an analogous fashion measure the motion The photographs in the illustration were taken at the Yerkes Observatory with the great 40-inch telescope Two separate spectra are there shown taken but three days apart on January 5th and 8th 1906 The star spectrum appears in each between the comparison spectrum of titanium and it is widened to make the lines more prominent and the whole greatly enlarged The violet end is toward the left, red end to the right Portions of the comparison spectra on both are cut away to bring the two closer The numbers on the top give the wave lengths Notice that all the lines in the lower spectrum are shifted much more to the right with respect to the comparison lines than in the upper spectrum This is specially noticeable at line 4501 and better still at 4481 A measure of the amount of these shifts gives the radial velocity of the star with respect to the earth The variable velocity in the line of sight of this star shows it is not a single star but a system Measures made by the writer on the star $\beta$ Trianguli show the following results where the radial velocities are given in miles per second relative to the sun The plus sign means that the star is increasing its distance from the sun and a minus sign that it is moving toward the sun

| Date | | Velocity in line of sight |
|---|---|---|
| 1908—Sept | 7 | + 33 miles per second |
| Sept | 8 | + 31 miles per second |
| Sept. | 18 | — 5 miles per second |
| Oct | 5 | + 1 mile per second |
| Oct | 12 | + 20 miles per second |
| Nov | 8 | + 18 miles per second |

The measures must be carried out with utmost care If the spectrum of the star is good with many well defined lines, the radial velocity (i e toward or away from us) may be determined to an accuracy of one-tenth of a mile per second Think of this when light travels at the rate of 186,000 miles per second when six hundred millions of millions of waves enter the spectroscope every second and when in addition the star is so far distant that its light even when traveling at such enormous velocities might take hundreds or thousands of years to reach us! To contemplate it makes our minds whirl at the enormity of space and causes us to bow down in reverence to the wonderful human intellect that can solve such problems!

Investigations of certain stars show us that at one time it may be moving toward our sun once in a few days or weeks the direction of motion may be reversed and it is traveling away from the sun The star of itself is unable to change its motion, and another body must be present so that variable velocities in the line of sight as in $\beta$ Trianguli denote that two or more suns are present in a system and they are in revolution about each other At our distance from the stars the

sideways displacement is not of sufficient magnitude to make the stars appear separately, and hence we have a comparatively new class of stars, those which appear as single even in the most powerful telescopes, but whose motions in the spectroscope show that they are really double suns. These are called spectroscopic binaries. Recent researches at the Lick Observatory, Yerkes Observatory and other places bring to our knowledge most startling results. Imagine two suns each many times more massive than our own, rapidly revolving about each other in a few hours! In addition to this comes the fact that at least one in every few stars so far investigated turns out to be not a single star but a system, and it has become necessary to reconstruct our ideas regarding the importance in the universe of this small ball which we call Mother Earth.

### Dying Pearls.

*(Concluded from page 168.)*

chill which can very easily cause its tender outer layers to contract and its beautiful luster to disappear Unfortunately the Thiers collar has been laid on red velvet, and this circumstance, too, can help to dull its shimmering surfaces day by day, for the color also, produced by chemical means, exercises a slow but sure influence. Besides it lies too near a window, and so the rays of light, too, have an injurious effect on it The directors of the Museum of the Louvre have long deemed the collar one of their most precious curiosities, but now, in consequence of the evident steady diminution of its value, they would like to sell it and with the money obtained for it procure a few more good paintings. Permission therefor, however, is refused by the executrix and chief heiress of the Thiers estate, and consequently the jewelers of Paris consider the collar an object of experiment by which it will be shown in how many years a pearl can "die away" when nothing is done for its preservation. How long pearls "live," that is, how long they keep their luster, has not yet been ascertained, but, as many instances, especially in the successive inheritance of heirlooms, prove, some preserve their fresh ness through centuries in consequence of the habitual gentle treatment they receive When treated thoughtlessly a pearl dies quickly

### Life Insurance and the Moral Responsibility of Employers.

BY DARWIN P KINGSLEY

The growth of life insurance and the development of a deep sense of responsibility on the part of employers of labor toward their employees are contemporaneous and kindred phenomena They represent a better knowledge of the value of human life and a recognition of the increasing demand now fairly made on the controlling forces of society, by age and industrial misfortune, as well as by infancy, congenital incapacity, and weakness

The middle-aged and the socially inefficient now form a relatively larger section of society than ever before There are two reasons for this The first is, that while there may not be as many children born now as formerly, among certain people, of the number born a much larger portion reach maturity In other words, the ratio of adults to a given number of births has increased. The second reason is that modern business methods and the modern corporation, especially the manufacturing corporation, have created new conditions and complications. They have added to those who join the dependent classes under a simpler life, those who become dependent because their active lives have been devoted to highly specialized work.

Highly specialized labor is constantly menaced by loss of occupation, and this menace increases as the age of the worker advances. Under the fierce competition

(Continued from page 172.)

which governs the greater portion of our industrial life, new processes, new methods, short cuts, labor-saving devices, new inventions, are all eagerly sought by the employer of labor. Some of these are revolutionary in their effects. They call for a readjustment of the whole plant. When that readjustment comes, the older men are invariably dropped. In short, the avenues which lead to employment, for all highly specialized labor, are practically open now only to youth. The middle-aged man enters with difficulty and the man past middle life substantially cannot enter at all. The man who did many things, none of them highly specialized, from twenty to sixty-five, is likely never to become entirely dependent upon society. The man who did some highly specialized piece of work which involved only a part of some specific thing, or even a part of a part, may be forced into the dependent class before he reaches old age, and when he joins that class he is much more helpless than the man who has done many things. It is probable that the specialist, altough he labored fewer years, rendered society the more valuable service of the two, and that therefore he has, morally at least, a clearer title to consideration. But however that may be, he is the inevitable product of the whole plan of society and business, and the obligation of the man who employs him and the interest of general society in what finally becomes of him, are clear and unavoidable. That this class must be shown how to protect itself against the menace which it constantly faces or that it must be helped outright after disaster or age come are compelling facts in the sociology of the times.

There can be no question that a system which teaches these people how to protect themselves against this menace, is more in harmony with the genius of our institutions than a system which coerces them into action or a system which finally places the burden of their support and care upon general society. It does not follow that a system which works well in Germany would work well here, or that a system which appeals to the needs of the people of Great Britain will answer here. There are distinct advantages in the German plan,—chiefly that it is compulsory and that the laborer is forced to make provision for certain benefits even though he may have no very intelligent understanding of the wisdom of the plan or its effects on society. There is a difference between the compulsion of government, which tells the workingman that certain things must be done, and the proposition of a corporation which tells a man what the conditions of his hiring are.

If the conditions named by the employer involve some system of life insurance, some system of deferred annuities, a man can study the question and take a position or leave it alone because it recommends itself to his judgment or otherwise. This is a slower process than the German method and probably for a good many years will be more expensive, but it seems to me to be in harmony with our notions of individual responsibility and the rights as well as the obligations of American citizenship.

The efficient employee, in specialized labor, has a fair claim to something beyond the returns contained in the ordinary contract of hiring. This right may be strengthened and its realization advanced, but it cannot directly be met, in this country, by governmental action. The capable worker deserves and should demand a programme of hiring under which he shall be entitled—and entitled by contract, not by the grace of his employer—to certain protection for his family if he dies prematurely, and to certain protection for himself if in the vicissitudes of industrial war he is shelved and wholly or in part compelled to join the dependent class.

There are sound reasons why corpor-

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES

WE ARE WELL EQUIPPED to manufacture some patented article, electrical and woodworking, on royalty or other satisfactory basis. Will entertain capitalizing. Electrical Box 71, N.Y.

Inquiry No. 8918. For manufacturers of Wyd's Electrocatalytic Sparking Plug.

## PATENTS FOR SALE

SENSATIONAL RIDING amusement device patent. Sure winner. Write for descriptive illustration. Sell reasonable. J. W. Bourke, 17 Cleveland St., Dorchester, Mass.

Inquiry No. 8982. Wanted the manufacturers of the Van Winkle Wm. H. & Sons and the Weber power motors.

FOR SALE.—U. S. Patent No. 911,542. An automatic brake to obviate danger to pedestrians and teamsters from depending live broken trolley wires by providing means whereby broken sections of such wires are automatically thrown out of the circuit and thus rendered harmless. Henry Nannenhorn, 71 Schiller St., Chicago.

Inquiry No. 9011.—For manufacturers of machinery, supplies, etc., to equip a small plant for the manufacture of iridium tipped gold nib making for fountain pens.

## FOR SALE

FOR SALE. Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all std. threads 8 to 40 in. Price only $40.50. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9016. Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

## WANTED

WANTED by a corporation engaged in the manufacture of agricultural machinery a competent draughtsman, reasonably well informed as to patent law, to take charge of its patent department under the supervision of its general counsel. Reply only by mail, addressing the Secretary of the advertiser, M. I. Lyon, 221 Seventh Avenue, New York City.

Inquiry No. 9023.—Wanted to buy silk machines from re-reeling, twisting, doubling in the final process of making it into clothes.

WANTED, partner to defray cost of patents on very striking and attractive toy. Guaranteed patentable. Rare opportunity for somebody. Address J. Thomas Huston, Henderson, Texas.

Inquiry No. 9029. Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9036. Wanted, the address of the manufacturers of "Cycle Ball Bearing Suspenders."

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9038.—Wanted the address of the Chipman Electric Purifying Co.

Inquiry No. 9043.—Wanted the address of Farney Safety Razor Co.

Inquiry No. 9046. Wanted machinery used for the manufacture of all kinds of fruit boxes, baskets and crates.

Inquiry No. 9049. Wanted to buy rotary brushes suitable for a shoe shining machine.

Inquiry No. 9052.—Wanted address of firms who install plants to manufacture nitrogen.

Inquiry No. 9055. Wanted address of parties interested in Egg Cleaning Machines.

Inquiry No. 9057. For manufacturers of glass and china balls, used as fixtures or ornaments on lightning rod equipment, also weather vanes for same purpose.

Inquiry No. 9058. Wanted firms who make machinery used for pulverizing soap-stone.

Inquiry No. 9060. Wanted to buy machinery to manufacture seed corn racks.

Inquiry No. 9063. Wanted to buy a plant for manufacturing muriatic acid.

Inquiry No. 9065.—Wanted to buy a second hand telephone generator.

Inquiry No. 9066. Wanted complete outfit for export for making rice-flakes and wheat-flakes.

Inquiry No. 9067.—Wanted the address of makers of the Standard Folding Typewriter.

Inquiry No. 9068. Wanted to buy machinery for manufacturing chewing gum, such as rolling, cutting or wrapping machinery.

Inquiry No. 9069.—For the address of firms making chain of the something like ladies' purses are made of.

Inquiry No. 9070. Wanted manufacturers of metal castings for art lamp shades.

Inquiry No. 9071. Wanted the address of parties making moulds for large concrete vases for flower pots.

Inquiry No. 9072. Wanted machinery for making fine chains such as used by jewelers, etc.

Inquiry No. 9073.—Wanted machinery to manufacture cocoanut oil, also the crude material.

Inquiry No. 9074. Wanted to buy old model ingenuity air steamboats such as were exhibited with nickel in the slot attachments in ferry houses, etc.

# A Home-Made 100-Mile Wireless Telegraph Set

Read SCIENTIFIC AMERICAN SUPPLEMENT 1605 for a thorough clear description by A. Frederick Collins of the construction of a 100-mile wireless telegraph outfit. Numerous adequate diagrams accompany the text. Price 10 cents by mail. Order from your newsdealer or from

A printed copy of the specification and drawing of any patent in the foregoing list, or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway, New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

(Concluded from page 173.)

tions should avail themselves in this work of the highly developed system of insurance and annuities presented by the responsible insurance institutions of this and of other States. Any effective system if established by corporations independently, will be based on the principles and methods used by the insurance companies, and therefore the work for obvious reasons is in the end likely to be more effectively and more economically done by men who are experts and specialists than by men who undertake it with no special training and with minds chiefly occupied by the demands of other lines of work.

I shall therefore assume that life insurance, and probably other types of insurance including accident and sickness insurance, as represented by existing corporations is not only well equipped to help in the solution of this problem, but is a part of the evolution of the times which has produced the problem itself, and is another illustration of the curious fact that in the processes of evolution a solution of a problem often appears at the same time the problem itself is evolved. For example, what might have happened in the enormous industrial activity of the United States and its necessary output of securities seeking purchasers if millions of people combining their small savings in the reserves of the great life insurance companies had not appeared upon the scene contemporaneously seeking securities in which to invest their money? The function of life insurance and of other types of insurance on the one hand and the obligation of the employer of labor to his employees on the other, bear, it seem to me, an identical relation.

Life insurance is already effectively at work. While the employer of labor has only in the most limited way used the idea or appreciated its beneficence, progress has been made toward the solution of this problem. Eliminating industrial companies and including only those companies whose business is supposed to be confined to people of means, we find the average policy the country over is a little under $2,000. In other words the mass of so-called regular insurance is held by people of small means. If now we add to these the millions who carry what is called "industrial" insurance, and the other millions who have so-called "fraternal" insurance we have covered substantially the whole insurance field. We comprehend an interest whose accumulations surpass those of any other single line of human endeavor except the accumulations of savings banks, and yet we have not gone outside of what may properly be called the laboring class. The energy of life insurance management, in other words, and the obligation which the laboring man feels toward his family have in their development far outrun the sense of obligation of the employer. We have now reached the point when the employer is beginning to do his part—but as yet he has only made a beginning. That he will do more is certain, that he will do much is almost equally certain. That existing insurance institutions will be utilized is, I believe, a necessity.

### Alloys Formed by the Compression of Metal Powders.

The ordinary method of preparing alloys consists in melting two or more metals together, and allowing the melt to crystallize after cooling. Can not the same alloys be obtained by compressing the component metals at ordinary temperatures in the shape of fine powders? Dr. W. Spring showed as far back as 1882 that under a pressure of 5,000 atmospheres the powders of the constituents of the Rose and Wood alloys will form conglomerates, the melting points of which nearly coincide with those of the alloys obtained by melting. In 1888 Hallock showed that by merely mixing at ordinary pressures the powders of the same constituents there is obtained a mixture

(Concluded on page 175.)

*(Concluded from page 174.)*

melting at a lower temperature than the melting point of the most fusible component By compressing zine and copper powders, Spring obtained a conglomerate which was distinguished from brass only by its slightly darker color

In spite of these partial results the problem had not so far been definitely solved It remained in fact to be seen whether, by augmenting the speed of fusion of the mixed metal powders, pressure really favors the formation of those compounds which are characteristic of alloys obtained by melting This question is answered by Prof G Tammann on the basis of recent experiments by G Masing

When submitting a mixture of filings of two metals forming neither a chemical compound nor mixed crystals (e g, zinc and cadmium or copper and silver) to a pressure of 4 000 atmospheres, and heating the conglomerate thus obtained the rising curve of temperatures is seen at a given point to slacken down after reaching a temperature 10½ deg C higher than that at which the whole is found to melt. As far as its thermal properties and its structure are considered this conglomerate is practically identical with alloys obtained by melting

Again by compressing under high pressure the powders of two metals forming a definite compound and capable of mixing in all proportions in a liquid condition and by heating the conglomerate thus obtained, two stopping points are found in the curve of temperatures The first of these points corresponds with the melting of a compound formed at the surface while the other corresponds with the formation of the alloy This is the case for instance, with mixtures of magnesium with zinc lead tin or bismuth The conglomerate composed of magnesium and antimony has only a single stopping point situated at 300 deg C below the melting point of antimony This corresponds with the formation of the compound $Mg_3Sb_2$.

The temperature then rises very rapidly in order to eventually fall down to the melting point of the alloy The third case investigated by Masing relates to the conglomerate of two metals forming an uninterrupted series of mixed crystals, such as magnesium and cadmium on the one hand and lead and thallium on the other When heating such conglomerates only a single stopping point is observed corresponding to the melting point of the most fusible component The form then assumed by the curve depends on the diffusion of the two components into one another

The conglomerates obtained merely by compression do not contain any trace of mixed crystals Microscopical examination thus only shows the existence of grains of copper and tin in recently prepared conglomerates If, however these mixtures be heated to 200 deg C (i e, below the melting point of the tin) there are found between the grains of copper and tin, *two layers corresponding to the* compounds $Cu_3Sn$ and CuSn respectively If these conglomerates be heated during 20 hours to 400 deg a layer of mixed crystals, corresponding to the formula $Cu_4Sn$, is found This proves that compounds of these metals are permeable to their constituents.

The following conclusions are derived from these experiments

The compression of two metals at ordinary temperatures will yield conglomerates containing only the pure metal i e neither compounds nor mixed crystals as characteristic of alloys obtained by melting. Mere compression thus does not activate diffusion sufficiently to bring about combination or the formation of mixed crystals If, however, heated metals (i e., with increased speed of diffusion) are submitted to pressure there is obtained not only a more coherent mass, but a portion of the metals is found to form compounds and mixed crystals, so as to produce a conglomerate which is very much like a real alloy

## THE COMMISSIONER OF PATENTS' ANNUAL REPORT

THE annual report of the Commissioner of Patents, Hon. Edward B. Moore, for the fiscal year ending June 30th, 1909, has recently been published and contains several useful suggestions for the improvement of the office of value to inventors and patentees.

Referring to the work of the office, he says:

"There were received in the last fiscal year 62,800 applications for mechanical patents, 1,186 applications for designs, 192 applications for reissues, 2,052 caveats, 7,509 applications for trade-marks, 1,001 applications for labels, and 138 applications for prints. There were 35,215 patents granted, including reissues and designs, and 4,547 trade-marks, 779 labels, and 211 prints were registered. The number of patents that expired was 22,779. The number of allowed applications which were by operation of law forfeited for nonpayment of the final fees, was 6,763.

"The applications for patents for inventions have increased over last year by between 4,000 and 5,000 cases. The applications for trade-marks, however, show an increase of only 42. The number of trade-marks registered shows a decrease of 1,598.

"The 'act to amend and consolidate the acts respecting copyrights,' which was approved March 4th, 1909, and which became effective July 1st, 1909, repealed the act approved June 18th, 1874, under section 3 of which labels and prints have been registered in the Patent Office. Consequently no certificates of registration of labels or prints have been issued since July 1st, 1909, except those evidencing registrations effected on or before June 30th, 1909.

"The money receipts from all sources were $1,975,919.97, and the expenditures $1,887,443.35, leaving a net surplus of receipts over expenditures of $88,476.62. The grand total of receipts over expenditures for maintaining the bureau from 1836 to date is now $7,060,547. This vast sum represents the earnings of the Patent Office, and the bureau is therefore more than self-supporting."

Owing to his success in securing additional appropriations from Congress in 1908, the salaries of the examining corps were increased on July 1st of that year, resulting in a noted decrease in the annual resignations. Owing to the additional force he was authorized to employ and the retention of the skilled examiners, the work in nearly all of the examining divisions of the office is practically current. He aims to keep the work current in all branches of the office, if possible, which is certainly a most laudable purpose, and one that should be carefully considered by Congress. He says:

"The rapid increase in the number of applications filed and the constantly increasing field of search embracing as it does not only United States and foreign patents, but also publications of every character, make it imperative that additional force be provided each year to prevent accumulation of the work."

He has asked for one new principal examiner and twenty additional examiners to further the work of classification of patents. There are now 930,000 United States patents, approximately half of which have been reclassified. Over 2,000,000 foreign patents and nearly 90,000 volumes of the scientific library remain to be classified.

The models formerly stored in the basement and on the first floor of the Patent Office building have been moved to another fireproof warehouse a short distance away.

Additional space for the storage of new volumes of foreign patents by at least 150 linear feet per annum should be provided for in the office library. An appropriation of $2,000 for this purpose, which it is thought will be sufficient for a period of five years, is recommended.

The space available for the storage of printed classified copies of patents is becoming crowded and the accommodations in the attorneys' and public search room are becoming insufficient for the work done there. One of the long hallways that has been set apart for this purpose is in a congested condition and is inadequate for the purpose. Some changes to afford temporary relief are suggested by remodeling the basement on three sides to conform to that of the Ninth Street front.

He believes that the time has arrived when measures should be taken to secure the construction of a new larger building in which ample room will be afforded to properly and promptly transact the business of the office. He says particularly:

"It is necessary that patents for new inventions should be issued with the utmost promptness after the application for patent has been filed for such inventions form the basis of vast industries, which inure not merely to the profit of the inventor, but to the benefit of the manufacturer, the laborer, the trader, the professional man, and the consumer, and to the commercial interests of the country in general. Great Britain and Germany have each recognized the necessity of providing ample facilities for the work of their patent bureaus, and have each recently erected new buildings for their patent offices, which are in every way more commodious and better adapted for the business of a patent office than the building which now houses the United States Patent Office, although the patent business of each of those countries is small when compared with that transacted in the United States Patent Office."

He urges that the new building be located near the Congressional Library on a square north of that building as embodied in Senate bill No. 3,954, introduced by Senator Daniel, January 24th, 1898. The surplus to the credit of the Patent Office in the Treasury Department of $7,060,547 he thinks would go far toward paying the expense of the building.

As to future desired legislation he continues his recommendation in previous reports by advocating an amendment to the statute which has for its object the shortening the course of appeals from the primary examiner (in *ex parte* cases) to the board of examiners in chief and the Commissioner by combining the board of examiners in chief with the Commissioner of Patents and his first and second assistants into a single tribunal, any three of whom shall constitute a quorum, to which all appeals shall lie, whether from a primary examiner or from the examiner in interferences and from which appeals would lie to the Court of Appeals of the District of Columbia. The elimination of one appeal, he states, would materially shorten the time required for the ultimate disposal of appealed cases and effect a considerable saving of expense to applicants. We believe there is much merit in this recommendation and trust it may receive favorable consideration by Congress.

A further additional provision recommended is the amending of section 4,889 of the patent law by requiring to be filed with the drawing two photographic copies thereof with the application. One of the photographic copies is to be kept in the file wrapper and the other is to be filed in secret archives in charge of the chief draughtsman, while the drawing itself will be kept constantly in the office of the examiner and will be available at all times for inspection in their respective divisions. He states there have been cases of fraud in withdrawing and substituting other drawings for the originals and that some such plan is needed to detect possible unauthorized changes.

We think it would be more practical for the Commissioner to have the negatives made of the drawing at the time the application is filed, and withhold the delivery of the filing receipt until the official photographer had certified the photograph as being an exact reproduction of the drawing.

The Commissioner advocates the formation of a "patent bar," and suggests before an individual be permitted to practise before the Patent Office he will be required to pass an examination as to his moral, legal, and technical qualifications before a committee appointed by the Commissioner of Patents, composed of officials of the office and patent attorneys of well-known standing in the profession, who shall conduct the examination under the direction of the Commissioner. The report of the committee is to be subject to his approval. This suggestion appears to us to be very appropriate.

In regard to the amendment and improvement of treaties with other countries concerning industrial property, it is proper to say Commissioner Moore has been most successful in securing advantages for American inventors. He says on this subject:

"I am gratified to report that during the last year a treaty was negotiated with Germany, which confers great benefits upon the American inventor. The patent laws of nearly all the foreign countries contain a clause providing that if an invention is not 'worked'—that is, manufactured or practised—in such country within a certain period, ranging from two to four years, the patent may be annulled. This treaty with Germany provides that the working of a patent in one of the contracting countries will have the same force and effect, so far as avoiding the revocation of the patent is concerned, as if it had been worked in the country in which the patent was granted. This treaty has practically assured to American inventors the protection of their rights in Germany during the full period for which the German patent is issued, contingent only on the working of the invention in one of the two countries.

"It is understood that Sweden has modified its laws to extend similar protection to other countries which do not require the working of the invention within a specified period, and negotiations are now pending with nearly all the European states for the promulgation of treaties of the same character. In order to assist in the negotiations of these treaties, I have been delegated by the Department of State, and with your permission I shall visit the capitals of several foreign nations to assist, so far as within my power, in the negotiations of such treaties, which if concluded will greatly extend the protection of inventors, manufacturers, and the industrial interests of this country, as well as those of the nations with whom such arrangements may be made."

He states the next International Convention for the Protection of Industrial Property is to be held at Washington, D. C., in May, 1911. About this he is most sanguine and enthusiastic. He says:

"The meeting of this convention is most important to the interests of the American inventors and manufacturers. The 21 nations which are adherents to this union will be represented by delegates having full power to negotiate agreements in respect to the reciprocal protection of patents, designs, trade-marks, and industrial models, which when ratified by their respective governments will have the force of treaties. The efforts of these conventions in the past have been crowned with success, the agreements relating to the reciprocal protection of patents and trade-marks having been ratified by all adherents, which comprise the leading commercial nations of the world, and the Congress of the United States has in each instance amended the patent laws of this country to accord with the terms of the international agreements concluded at these conventions.

"Not only are the members of the union represented by delegates, but all other civilized nations, not members of the union, are invited to send representatives in the interest of furthering the reciprocal protection of industrial property. It is expected that at this coming convention a strong effort will be made to harmonize the laws relating to patents and trade-marks throughout all countries in such a manner that adequate protection will be given to an inventor, no matter of what country he may be a citizen, without the necessity of obtaining expensive patents in each of the several countries in which his invention may be used or sold. It is also proposed to perfect and extend the international registration of trade-marks and thus further the reciprocal protection of commercial industries."

## THE ALL-STEEL CAR THE CAR OF THE FUTURE

FOR many years past the SCIENTIFIC AMERICAN has strongly advocated, on grounds of public health and safety, the building of all-steel cars for railroad service, and we are therefore much gratified to learn that the Pennsylvania Railroad Company is adding to its steel-car equipment at a rate which promises, before many years, to eliminate the present wooden car, and provide that great system with an all-steel passenger car equipment. It was on August 13th, 1906, that that railroad announced that all future passenger equipment would be built of steel and that the design would be such as to render it indestructible either by collision or fire. In planning the cars and establishing those standard types which are now being copied in all the new equipment, no expense has been spared to build a coach which should provide the greatest possible strength, and finish it with an inside lining that should be absolutely unburnable and possess the added and not inconsiderable advantage that it would be a poor conductor of heat and noise. The first order, placed in November 1906, was for 100 cars. Subsequent orders have been given, and there are now in service 245 coaches, 10 dining cars, 21 combination passenger and baggage cars, 29 baggage cars, 18 postal cars, and 1 company car, making a total of 324 steel cars. Furthermore, the Pullman Company has been building for the railroad during the past four years some all-steel parlor and sleeping cars. About 500 of these will shortly be placed in service. With the present steel equipment and some 350 cars to be ordered during the present year, the Pennsylvania railroad will in a short while have in service 990 of its own steel passenger cars and about 500 steel Pullman cars.

## ENGINEERING.

In a paper recently read by Mr Henry Hess before the American Society of Mechanical Engineers on the power lost in belting, it was shown that 90 per cent of the power transmission lost was due to journal friction. This may be materially reduced by substitution of ball for plain bearings, provided care be taken to suit the size of the balls to the load.

The Committee of the American Railway Maintenance-of-Way Association in a recent bulletin takes up the subject of rail specifications For Bessemer rails of 85 to 100 lbs. it recommends the following composition Carbon, 0 45 to 0 55, manganese, 0 85 to 1 15, phosphorus not to exceed 0 10, and sulphur not to exceed 0 075 The recommendations for open-hearth steel for the same weight of rail, carbon, 0 68 to 0 76, manganese, 0 75 to 1 00, phosphorus not to exceed 0 04, and sulphur not to exceed 0 06

The two latest German dreadnoughts are to be equipped with turbines, and special interest attaches to the fact that two rival types of turbine, the Parsons and the Curtis, will be tried out against each other The "Heimdal" will be propelled by triple screws operated by Curtis turbines, and the sister ship will be equipped with Parsons turbines of equal contract power

A method of simultaneously excavating and lining vertical shafts is contemplated in one of the contracts for the Catskill water supply In the shaft will be suspended a lining platform, from which the concrete forms will be erected and concrete laid The excavating will be carried on below, the material being hoisted through a hole in the center of the platform.

We recently noted in these columns the rapid increase in the weight of locomotives A similar growth is taking place in the cars, the Pennsylvania Railroad Co having recently asked for tenders for 10,000 coal cars of 70 tons capacity and an overload capacity of 10 per cent As the steel in the cars will weigh 20 tons exclusive of the wheels, the maximum weight of car and load may reach 100 tons

Apropos of marine turbines we note that Messrs Parsons & Co, recognizing the advantages of twin-screw propulsion, as proved in the Curtis equipment of the scout "Salem," have developed a modified Curtis partial admission turbine which they are to install in one of the new 5 200-ton 26-knot British scouts. A sister ship will have Curtis turbines The Parsons turbines will weigh 340 tons, and guarantee full power on 13 pounds of dry steam per horse-power per hour The Curtis turbine will weigh 250 tons and guarantee 12 5 pounds of superheated steam

There are persistent reports that the Hamburg American Line is about to build two huge steamers which will rival the White Star liners Olympic and Titanic, which are to be in service during 1911 The reported dimensions are Length, 850 feet, beam, 92 feet, and depth 66 feet Reciprocating engines of 48,000 horse-power will drive the ships at a speed of 21 knots

A recent bulletin of the United States Geological Survey gives some statistics of producer-gas power plants in the United States which are very favorable There are over 500 plants in operation, aggregating 115,000 horse-power The government testing plants at St. Louis and Norfolk show a fuel consumption of as low, under favorable conditions, as 0 95 pound per electrical horse-power Comparative tests of 75 grades of bituminous coal under steam boilers and in producers show a ratio of 2 7 in favor of the latter

One of the most important branches of the general schema for the development of Japan is the extension of her railroad development along predetermined lines which have been laid out with an eye to the development of the country considered as a unit A notable event in this development was the recent completion of the railway between Hitoyoshi and Kagoshima, which connected up the last link in the trunk line running throughout the full length of the empire The total length of the line is 1,750 miles, and the distance from north to south of the island can now be covered in five days and nights. At the close of the fiscal year 1907-1908 4,453 miles of state railways were opened to traffic and 455 miles of railway controlled by private interests

A promising installation of a windmill-electric plant has recently been completed at Worcester, England, by J G. Childs & Co., of London It consists of a 24-foot wind turbine carried upon a 75-foot tower The generator is located at the foot of the tower, the battery and switchboard in one of the outbuildings of the house. Overhead copper cables carry the current to the battery some 455 yards distant. The generator which runs at 400 to 800 revolutions per minute is driven by a 5-inch belt from the vertical shaft of the wind turbine. It has a maximum output of 4 kilowatts with a normal pressure of 70 volts. The plant runs about 100 lights in the house, and serves also to drive a chaff cutter, a circular saw, and a root-pulping machine.

## ELECTRICAL.

A company has been formed in London to introduce and encourage the use of electricity in the poorer districts of the city The company agrees to wire and supply any apartment of three rooms and over with tantalum lamps, charging five cents a week per lamp from April to September and seven cents a week for the rest of the year The lamps however must be renewed by the consumer

A new mounting for metallic filament in lamps has been devised in Germany The mounting provides for the shrinkage of the filament which is not always uniform, and for this reason each filament is supported at its lower end on a small spring which is covered with a paste of finely powdered tungsten so as to prevent it from being consumed by the heat of the incandescent filaments

The use of the telephone for train dispatching is slowly spreading The Gulf, Texas & Western Railroad is equipping its line with a telephone system for train dispatching between Jacksboro and Benjamin Texas. The road connects the Chicago, Rock Island & Gulf and the Wichita Valley railroads When the telephone system on the Spokane division of the Great Northern Railway is completed there will be 2 100 miles of this railroad operated by means of the telephone

A hydro-electric plant in the Hakone Mountains about 36 miles from Yokohama, Japan has recently been completed and is particularly interesting for the fact that much of the apparatus used is of Japanese make The Shibaura Electric Manufacturing Company of Tokio has built the 600-kilowatt air-cooled, oil immersed transformers to be used at the sub-station in Yokohama. A large number of the high tension insulators used on the line are of the Shibaura type About one-third of the line is supported on towers which is a new departure for Japan At the power station the water is carried over a distance of 15 000 feet in two parallel pipe lines that lead to the turbo-generator units The upper half of the pipe lines consists of riveted pipes made by the Shibaura Company The plant comprises two 2 000-kilowatt alternators and the current which is generated at 3 450 volts, is stepped up to 46,000 volts for the line

In a recent number of the Electrical World appears an interesting article on the wireless telephone and the author arrives at the following conclusions "It is, then quite evident that future systems of wireless telephony must either eliminate the use of microphone transmitters or find types far in advance of those used to-day In addition to this, some more powerful and more reliable oscillator must be substituted for the arc If no great difficulties arise in its operation and its cost be sufficiently reduced this substitute may be the high frequency alternator With the few weak points of the present system removed and the useful parts of the apparatus retained, the wireless telephone will come into all the uses to which it is adapted but the elimination of the defects will involve a departure from present methods Until these are discarded, attempts at commercial wireless telephony will be futile"

The following useful electrical shop kink was published in a recent number of the Electric Railway Journal describing a method of soldering broken or burned-out wires without removing them from the armature "The damaged wire is raised a little way out of the slot. The insulation is then scraped off for a few inches and the ends of the broken wire are filed off smoothly after which a piece of wire is cut to fill the gap One end of the inserted wire is then butt-ended with the armature wire and the ends heated by a gas torch until they are red hot Upon this a little borax is applied as a flux, and then some silver solder is inserted between the ends. When both splices are completed in this fashion the bare wire is wound with silk, as the latter takes up less space than tape After the silk has been covered with insulation the coil is ready to be returned to the slot During the operation of heating with the torch the adjacent wires are protected by fiber barriers"

It is reported that at the time of the rescue of the crew of the steamship "Kentucky" by the "Alamo," which had been summoned by wireless telegraphy, the wireless apparatus had almost been put out of commission by the water that partially submerged the dynamo. By wrapping the dynamo with tarpaulins it was possible to keep the machine running until help arrived This is not the only case of a rescue due to the help summoned by wireless telegraphy, and on a previous occasion the apparatus was put out of commission by the encroachments of the water It has been suggested that storage batteries should be used to supply the current, because they could be placed where there would be no danger of injury by water But as storage batteries would be impractical owing to the motion of a vessel in a storm, some arrangement should be provided for placing the dynamo and a gasoline engine for driving it well above the danger line.

## SCIENCE.

Recent experiments have proved conclusively that coal dust which has been ground to a state so fine that it will pass a 200-mesh sieve, will explode from contact with either a naked flame or with the arc of an electric current

The building of an observatory on the rim of the great crater of Kilauea has been advocated for several years. The prospects are now brighter than they ever were, and it seems likely that the observatory will be built as part of the College of Hawaii

A recipe for a non-shrinking alloy to be used in duplicating patterns, is given as follows by The Metal Industry Tin, 50 pounds, zinc, 50 pounds This gives a tough hard metal that runs well if a good grade of zinc is used The addition of 2 pounds of bismuth will render it even more fluid and enable it to be poured at a lower temperature By using heavy sprues and pouring cold the shrinkage which is slight, may be largely overcome

Prof. E E Barnard recently obtained a photograph of Halley's comet showing a tail one degree long The comet is beginning to wake up Mr Ellerman will sail for Honolulu on March 8th to observe the transit of Halley's comet across the sun's disk He is sent out by the comet committee of the Astronomical and Astrophysical Society of America He takes with him a good 6-inch portrait lens by Brashear and a 6 inch equatorial mounting lent by the Lick Observatory He is perhaps the best possible man for the work, and will be thoroughly equipped to obtain the best results

During the night between October 7th and 8th, 1909, a meteoric stone fell to earth on the farm of Mr W P Nickerson, of Norwood Mass The meteorite is a ham shaped mass of very hard gray stony material, much corrugated on the surface, about two and one-half feet long in its greatest dimension one foot to nearly one and one half feet broad and varying from one foot to one-half foot in the third dimension Its volume was estimated as about 1 75 cubic feet Its weight as perhaps 275 pounds, and its density as not much over 2 5

Besides Halley's Comet two other comets may be expected in 1910 The first of these is Tempel's, discovered July 3d, 1873, at Milan It has a period of 5 75 years It was observed in 1878 1894 1899 and 1904 It last passed perihelion in November It ought therefore, to be expected this spring

The second of the expected comets is that of Arrest, discovered in 1851 and the return of which is expected in the summer of this year It was observed in 1857, 1870, 1877 1890 and 1897 It was unfortunately placed in 1903 and therefore could not be observed

The chief purpose of the sound proof room at the University of Upsala is the insuring of perfect freedom from sounds from outside By building it on platforms of thick lead and cement and by constructing its walls of many thicknesses of felt, cork, asbestos, and other bad conductors of sound vibrations, the principal object was attained The room is so quiet that the beating of one's heart or the creaking of one's muscles is at once heard on taking up a position within its closed doors and windows and the only defect of it as a laboratory for acoustic experiments is that ventilation is absent, and no one can remain in it for more than an hour at a time

Prof Lipmann announced before the Academy of Sciences that Madame Curie has obtained a tenth of a gramme of polonium with which she has been experimenting Polonium is a radio-active element discovered by Madame Curie as early as 1898 but not obtained before in sufficient quantities for elaborate experimentation From the brief reports which have been received it would seem that polonium in its earlier stages is more radio-active than radium, but it loses its power very much more rapidly It seems reasonably certain that polonium is identical with radium F, one of the series of metals produced by the decomposition of radium The particle of polonium obtained by Madame Curie is not entirely isolated, but was combined with several tenths of a milligramme of another body

A special investigation of the motion of the bridge of the violin has been made by J W Giltay and Prof M De Haas of Amsterdam They conclude from their experiments that the bridge of a violin performs a parallel as well as a transverse motion, and that the timbre of the tone is modified greatly when the intensity of one of the motions is altered and the other motion is left unchanged as nearly as possible They have also explained the action of the mute, and the influence which the use of too thick or too thin a bridge has on the sound of a violin The mute is commonly supposed to "dampen" or "deaden" the sound If the mute caused nothing but a general damping by reducing the bridge motion, the mute would only weaken the sound, and the same effect would be obtained by bowing softly on a violin without a mute as by bowing hard on a violin with a mute That, however is by no means the case, as every one knows.

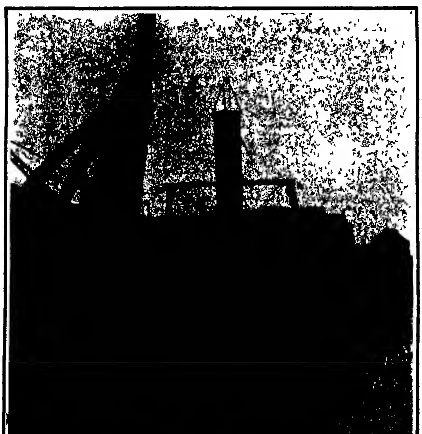
# A NEW TYPE OF SELF-DISCHARGING COALING VESSEL

BY F. C. COLEMAN

The new system of belt-conveyor discharge has been installed by William Doxford & Sons, Ltd., in a new vessel—the steamship "Pallion"—which they have recently built at the Pallion shipyard, Sunderland, England, to the order of the Dunrobin Shipping Company, Ltd. of Newcastle-on-Tyne. This vessel has a length between perpendiculars of 270 feet, and a carrying capacity of 3,100 tons on a 17 feet 10 inches draft. The machinery, comprising triple-expansion engines and multitubular boilers is placed aft. The cabin accommodation is fitted in the bridge and the crew space in the forecastle, while the navigation accommodation is about midships. The inner bottom is raised and sloped upward in the wings and built into the sides of the vessel forming a suitable incline for gravitating the cargo to the conveyers, and also giving the vessel the advantage of being about half loaded when in ballast and bunkers. In the center line is constructed a slope-top fore peak throughout the hold and between this tunnel and the tunnel extending from the engine space to the raised portions of the double bottom are placed the conveyer belts of the Robins pattern one on either side of the vessel. The sides of the tunnel below the level of the hatchways over the belts are open for free access to the belts and carriers at all times. Over these conveyor belts are placed strong iron guide plates extending the full length of the hold and partially covering the belts leaving a 24-inch hatch over a 36-inch belt. This space is covered in the holds by cross-laid hatch covers, 9 inches in length and 3 inches in thickness, which support the cargo and leave the conveyors to work without carrying the load. At the after end of the hold a portion of the hatch, over which the 9-inch hatch cover is omitted is covered by a horizontal iron slide door operated by a ratchet in the tunnel. On the foreside of the bulkhead is constructed an access chamber in free communication with the tunnel which is of such a form as partially to protect the slide door from the cargo when loading, and in the floor of this projection of the chamber is fitted a flap hatch to give access to the hold from the tunnel. At the after end of the cargo space the conveyers rise from the horizontal and pass upward in iron chambers through the machinery space, and thence into the conveyer-driving engine room and discharge the load into guide shoots in the stern of the vessel. These carry the load on to return belts, which are extended forward both sides on the deck. In a simple form these conveyers would terminate at the fore end of the machinery space, or poop front and the load would be delivered into side shoots which telescope and are adjustable for loading barges on either side of the vessel, the shoots being suspended from derricks or other suitable means. In cases where the discharge is required at a higher level than is attained at the poop front and a large range of elevation is necessary, as for instance, for delivery on high quays into trucks and into barges alongside, the conveyors are carried forward and hinged at the poop front, and the delivery end is suspended by suitable tackle from twin masts or framework, and is raised or lowered according to circumstances, delivering the load into telescopic shoots suspended therefrom. When the delivery is into trucks, the "offside" belt delivers amidships into a cross conveyor suspended on the masts, which carries the load to the shore side and delivers by shoots into the trucks. A development of this principle has, however, been applied to the steamship "Pallion," as, in order to obviate the use of delivery shoots, which results in considerable damage, the terminal conveyors are carried in swivel booms, which are raised or lowered and swung overboard to the points of delivery, thus permitting of the cargo being conveyed direct to the truck or barge without shoots. These booms may also be swung across to the reverse side of the vessel, so that both booms can deliver simultaneously into trucks or warehouse. Another important feature of this discharging arrangement lies in the method of delivering the cargo onto the belts from the hold, and enabling the operator to have full control and free access at all times to the conveyers and to the face of the cargo. He may thus superintend and direct the continuous flow, and be in a position promptly to correct any tendency of the cargo to bridge or to choke the aperture leading to the belt, which, being the smallest space the load has to pass through, insures a continuous and uninterrupted delivery.

View of the hold.

The coal falls by gravity onto a conveyer beneath the floor by which it is carried along to the elevator belts of the discharge spouts.



The coal is taken from the bottom of the hold and discharged at an elevation of 40 feet above the water by conveying and elevating belts operated on the ship. Rate of unloading 500 tons per hour, cost two cents a ton.

A NEW TYPE OF SELF-DISCHARGING COALING VESSEL.

The unloading of a cargo of coal is carried on as follows. Presumably the holds are full and the cargo lying solid, except under the overhang of the chamber on the bulkhead over the slide door, at which point the space is naturally only partially filled. The slide door in the covers over the conveyers is drawn back by the operator in the tunnel, and the loose coal over it immediately travels on to the conveyers, which may or may not have been started. If running, then the flow continues; if standing, no difficulty arises because the conveyer is only filled at that point, and the aperture becomes blocked and only clears and flows when the belt is started. Then, if no "bridging" occurs, the after part of the hold is rapidly emptied on to the conveyer which is carrying it on deck and into the receiving trucks or barges. If, however, any "bridging" is threatened, the operator in the tunnel ascends to the chamber, and has free access over the aperture to correct any block. If "bridging" occurs higher in the hold, than he breaks it by means of a pinch bar through perforations in the chamber sides. When the after end of the cargo has run to its natural angle of repose, the operator now in the hold merely removes the first cover and places it aft of the aperture allowing another portion of cargo to run, he being in a free position to maintain the run and correct any tendency to bridging and to abnormal rushes. If such do occur and incline to block the aperture, he again corrects this and, having run so much more, he removes the next segment of cover, and so on, gradually transferring the aperture from the after end to the fore end of the hold. The wing tanks and central tunnel being sloped, the cargo gravitates to the aperture, and the finals are manipulated by the operator, one man being on each side of the hold. An important feature is the inclined shoot, over which all the cargo passes on to the belt. This shoot is carried on travelers on the guide plate sides, and is moved by the operator in the hold forward from stop to stop to correspond with the movement of the aperture thus allowing two men to manipulate a whole cargo at the rate of 500 tons per hour. It is estimated that in regular working the steamship "Pallion" will be unloaded in six hours, or allowing for stoppages in moving barges, etc., seven to eight hours, and this too with but one stoker, one engineer, two laborers in the hold, and two adjusting the shoots or booms into the craft. The total cost of discharging the cargo of the "Pallion" will not exceed $60, including the upkeep of the gear, and it is affirmed that the cost of discharging a similar cargo at, for instance, the port of Hamburg, is about $560, and that in the work no fewer than 110 men are employed for about eleven hours under favorable conditions.

A steamer such as the "Pallion" is independent of shore labor, and so may avoid the frequent delays arising from labor troubles. The number of men required is so small, and the time occupied so short, that it would be a simple matter to agree with the crew of the vessel that they receive a fixed extra wage, and the discharge of the cargo become part of their ordinary duty. A liberal estimate of the cost of discharge, under such conditions, would not reach the sum of two cents per ton; and at this cost the cargo is also weighed.

---

Roof Paint.—Mix 35 parts of powdered clay slate, 30 of powdered mica slate, 35 of powdered American rosin, with half the quantity of pure coal tar and boil until an easily brushable mass is obtained.

# NOVEL ELECTRICAL APPLIANCES

BY PERCY COLLINS

The largely increased use of electricity for illuminating distilleries, wine-cellars, etc., has rendered obsolete many appliances which were formerly in use—especially those which consume coal-gas when in operation. Hence arose a demand for up-to-date inventions designed to meet the conditions imposed by progress. Few recent patents illustrate more strikingly the manner in which the ingenuity of mankind keeps pace with the exigencies of modern trade than those which are illustrated in the accompanying photographs. The patentee and manufacturer of these original electrical appliances is Mr Frederic Hughes, of London, England, and it is to this gentleman that the present writer is indebted for permission to describe and illustrate the apparatus in question. In the case of the electric search-light or cellar-torch, Mr Hughes claims that the appliance stands alone, being the only perfect, clean, odorless and reliable invention for thoroughly examining brewers' casks, vats, refrigerators, spirit or oil jars, etc.

The main details of the cellar-torch may be appreciated by reference to the accompanying photographs. The reader will see that it consists essentially of a powerful electric glow lamp of peculiar design, supported at the end of a suitably curved rod The circumference of this lamp is so small that the appliance can be used effectually through any orifice not less than half an inch in diameter

The advantages of this new cellar-torch will be most readily perceived if we compare it with the older appliances which it has superseded The contact of a gas jet, or a taper flame, with a cold surface (such as the inner wall of a cask or jar) immediately produces a deposit of soot, which may be too slight to attract the notice of the searcher, but will nevertheless discolor and injure to a greater or less extent the fluid with which the vessel is ultimately filled Similarly, when gas is used to "nose" casks, the products of combustion combined with the $CO_2$ already in the cask and the pungent odor involved conceal the mustiness and thus deceive the examiner, who accordingly certifies as clean a vessel which, as a fact, is far from being so With the patent searchlight or cellar-torch the examination may be prolonged indefinitely without in the least affecting the actual odor of the vessel's interior

As the heat generated by the lamp of this cellar-torch is very slight, the appliance may be employed for the examination of vessels containing all kinds of inflammable fluids or gases without the smallest risk of explosion. Each torch may be fitted at will with an oblong or circular mirror, which is screwed to the extremity of the appliance beyond the lamp Upon being passed into the jar or cask, a slight pressure against the side or bottom of the vessel causes the mirror to assume a horizontal position, and by this means a view of the *under* surface of the vessel is readily obtained The advantages of this device will be at once apparent to the practical reader, who will readily perceive that by no other means can the whole interior wall of a closed vessel be so thoroughly explored Indeed, for the thorough examination of the interiors of bung staves, bushes, boiler tubes, etc., there is no more perfect appliance obtainable than Hughes's cellar-torch fitted with a reflector of suitable shape

In conjunction with his patent electric torch, Mr Hughes has recently introduced another novelty in the thermo-cere or wax-melter This is an ingenious appliance by means of which a perfectly controlled supply of melted sealing- or bottling-wax may be obtained. Like all the most important patents, the apparatus is simple in design and effective in use. When connected by means of the flexible wire with the source of electrical current it is held in the left hand—the right hand being perfectly free for use A stick of wax is fitted into the holder and held in place by means of a screw clip. The left thumb (overcoming a spring) presses the wax downward against the heating receptacle, and by slightly inclining this the melted wax flows through a lip on to the letter, bottle, or other object which is to be sealed Of course, as the wax melts, the stick shortens, and to complete the melting of the entire stick a slight movement of the hand downward on the handle enables the thumb further to press the wax until the whole stick is consumed—the wax holder traveling in a grooved socket.

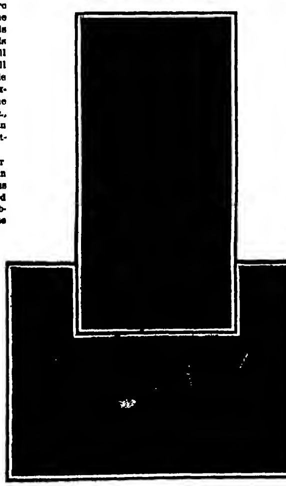
Whenever it becomes desirable to check the flow of melted wax, the pressure of the thumb is relaxed, when the spring causes the wax to rise just sufficiently to free it from the heating plate. A few of the advantages of the thermo-cere may be enumerated. In the first place, the appliance may be used in the most confined space, and in any circumstances, with absolute safety from the fire risk which is so constant a danger wherever naked gas jets and flexible rubber tubes are employed. Again, the greatest possible economy in the use of wax is obtainable, there being no possibility of waste through carelessness, for the reason that melting is automatically stopped the instant that

Wax melter in use, sealing bottle cork.

The electric wax melter.

the appliance leaves the hand No discoloration or smoking of the wax is possible, and the most delicately tinted sealing-wax will remain perfectly true to the original shade Finally, the sealing can proceed continuously, and in any position, the appliance needing no preliminary preparation, while all splashing or dropping of the wax is entirely avoided The thermo-cere may therefore be used for sealing letters, postal packets, etc, while articles of value may be safely left in close proximity without the slightest risk of their catching fire

The flexible electric cellar-torch.



Cellar-torch heads, showing lamp and mirror (detached).

NOVEL ELECTRICAL APPLIANCES.

## The New Agricultural Fertilizers.

The manufacture of fertilizers is one of the most important of chemical industries, but this manufacture, together with the exploitation of the nitrate beds of Chile and the potash deposits of Stassfurt, is now in a critical stage of development, owing to the increasing production of nitrogenous fertilizers by the fixation of atmospheric nitrogen, and also to the results of recent experiments on the fertilizing effect of extremely minute quantities of totally new agents. The properties of both classes of these new fertilizers are briefly described by René Vallier in Revue de Chimie pure et appliquée.

### I NITROGENOUS FERTILIZERS OBTAINED FROM THE ATMOSPHERE.

*Nitrates* Neutral nitrate of lime, containing 13 per cent of nitrogen, has been manufactured at Notodden, Norway since 1905 It is an excellent fertilizer and equal in all respects to Chile nitrate It can be mixed with superphosphate without causing appreciable loss of nitrogen or retrogradation of phosphoric acid Its hygrometric character makes its application somewhat inconvenient, but it possesses, in contrast with Chile nitrate, the advantage of adding to the soil lime, an indispensable plant food, instead of soda, the accumulation of which may be injurious to vegetation

It appears probable that Chile saltpeter will, before long, be supplanted by nitrates obtained from atmospheric nitrogen The Birkeland Eyde and other processes now in use are commercially practicable in their present form, only where water power is cheap, but these processes are susceptible of great improvement An efficiency equal to that of most other processes of industrial chemistry would make it commercially feasible to produce nitrates everywhere At present the nitric acid obtained from the air is neutralized with lime, while most of the world's production of sulphuric acid is employed in the manufacture of superphosphates If this nitric acid could be used to convert the tribasic calcium phosphate into the superphosphate an enormous saving could be effected and a fertilizer produced which would contain both soluble phosphoric acid and nitrogen in a form suitable for assimilation, and would drive every other nitrogenous or phosphated fertilizer out of the market.

*Cyanamides* The difficulty of applying the light cyanamide powder has been overcome by adding a little water, which combines with the quicklime of the crude cyanamide and forms a coarse powder called granulated cyanamide which is much more convenient in use A still better form is oil cyanamide, made by mixing the fine powder with 4 per cent of crude petroleum The proportion of nitrogen in commercial cyanamide has been increased by improvements in manufacture from 15 per cent to about 20 per cent, that of pure calcium cyanamide being about 35 per cent Cyanamide has now fairly entered into agricultural practice The trust which controls the sale of the product in Germany and Italy sold 3,000 tons of cyanamide in the first half of last year

Calcium cyanamide ($CN_2Ca$), treated with water and carbon dioxide yields dicyanamide ($C_2N_4H_4$) in the form of nearly insoluble colorless crystals, which contain 66 per cent of nitrogen and form the richest nitrogenous fertilizer ever produced In some cases the cost of production of dicyanamide may be counterbalanced by the economy in transportation Applied to wheat in the quantity of 30 or 40 pounds per acre, it has produced excellent results

Guillin has proved that more than one-fifth of the nitrogen of cyanamide is converted into ammonia in one week and more than one-third in two weeks, by the action of soil moisture Muentz and Nottin observed in two months a production of nitric acid corresponding to 11/12 of the nitrogen of the cyanamide added to the soil

The poisonous action on plants which was at first attributed to cyanamide fertilizers appears to have no existence or to be due to impurities The germinating power of wheat treated with pure cyanamide or dicyanamide is not diminished but is sometimes increased Muentz and Nottin however, observed a temporary arrest of growth after the application of cyanamide in hot dry weather, and therefore advise the selection of a wet period for its application

### II FERTILIZERS CONTAINING MANGANESE

Manganese is widely distributed in nature and plays an important part in the formation of the diastases which are the principal agents in vegetable synthesis Nagaoka, in Japan applied manganese sulphate to rice plantations in quantities equivalent to from 10 to 50 pounds of $Mn_3O_4$ per acre, and obtained increases of crop of from 32 to 37 per cent. The beneficial effect persisted to a smaller extent, through the following year Manganese chloride, a waste product of the chlorine industry, exerts a similar action.

in Europe. Voelcker and others have obtained increases in the crop of wheat up to 20 per cent from the application of from 25 to 50 pounds of manganese sulphate per acre Excessive doses (100 pounds) diminished the crop Similar results were obtained with oats

Grégoire, Hendrick and Corpiaux observed little benefit from the application of manganese to sugar beets, but Gasola obtained increments of 46 per cent in roots and 26 per cent in sugar from manganese chloride and of 24 per cent in roots and 55 per cent in sugar from manganese sulphate—the chloride diminishing and the sulphate increasing the richness of the juice

With flax Gurola obtained the surprising increase of 54 per cent in totally dry weight from manganese chloride, and 31 per cent from manganese sulphate He concludes from his analyses that the manganese applied is assimilated by the plants and that the difference in molecular weight of the chloride and sulphate determines the degree of influence on the formation of diastases

But the effect cannot be wholly due to the manganese which is assimilated, for Bertrand found no more manganese in oat plants, the growth of which had been increased by manganese, than in the control plants to which no manganese had been applied And recent American experiments have proved that fertilizing agents act partly by destroying the toxins left in the soil by the preceding crops Unstable manganese salts might be expected to promote the oxidation of these toxins Manganese oxide, traces of which occur in most soils, is entirely inert The greatest proportion of successes has been obtained with manganese sulphate.

III STIMULANTS AND POISONS

American experimenters have revived the old theory of De Candolle, and proved that infertility may be due to poisonous excretions It is conceivable that minute doses of powerful poisons might destroy these excretions or prevent their formation

*Copper Salts* The salts of copper have long been employed for the purpose of destroying fungous parasites of the grape, and fields of young grain can be freed of certain noxious weeds without injuring the grain plants by spraying with a 5 per cent solution of copper sulphate Quite recently Bréal has increased the yield of maize by from 27 to 86 per cent by soaking the seed corn in a copper bath and then drying it before planting The bath was composed of 3 parts by weight of copper sulphate, 30 parts of starch and 1,000 parts of water

*Zinc* Javillier, inferring, from the presence of zinc in many plants that this metal must perform some function in vegetable physiology made an extensive series of experiments which proved that infinitesimal quantities of zinc promote the growth and multiplication of mold and yeast fungi and some chlorophyl-bearing plants. For example the growth of a certain mold was stimulated by cultivation in a medium containing 1 part of zinc in 50,000,000, the maximum increase was produced by proportion between 1 in 10,000,000 and 1 in 25 000 and still stronger solutions exerted an unfavorable or toxic influence Micheels and De Heen find that zinc salts promote the germination of wheat

*Alum* The large proportion of alumina found in the ash of certain exotic plants (more than 50 per cent in the Australian tree *Orites excelsea*) led Yamano to try the effect of aluminous fertilizers Common alum, added in the proportion of 1/5 per cent to the water in which young barley plants were growing quickly killed the plants, but proved much less injurious to barley growing in the ground A distinct fertilizing effect, manifested by increase of crop was observed to follow the application of 1/20 per cent and 1/500 per cent solutions of ammonia alum to barley and flax the effect of the ammonia having been carefully eliminated

*Magnesia.* The presence of magnesia in all plants and in all soils long ago suggested the employment of magnesia as a fertilizer Tribot's recent study of the influence of magnesia in the transformation of saccharose proves that magnesia can act as a ferment. Magnesian fertilizers were formerly employed, to some extent and with good results In recent experiments magnesia has been found to increase the crop of grain potatoes and beets chiefly by promoting the assimilation of nitrogen

*Bromine* Aso finds sodium bromide stimulating in very small doses and poisonous in larger doses to beans growing in pots One part of bromide to 50 million 5 million and 1 million parts of earth produced increases of crop of 93, 48 and 29 per cent, respectively

*Iodine and Fluorine* Potassium iodide, applied in dilute solution, appears also to act as a stimulant or a poison according to the dose Aso and Suzuki obtained a large increase in crop of rice from about 1 40 pound of the salt per acre but very little increase from ¼ pound while Hollrung diminished the crop of sugar beets by one-fourth by applying about 4 10 pound per acre. Analogous results were obtained by the same experimenters, with sodium fluoride, applied to the same crops.

*Rare Elements* Cerium, like manganese, appears to act as a ferment Aso finds thorium rather injurious than beneficial to vegetation Nakamura has increased the yield of rice, growing in pots, by 70 per cent., by mixing with the soil 1 100 000 of its weight of lithium carbonate, but a dose 10 times greater produced a smaller increase (55 per cent), caesium carbonate, in the same doses, produced increases of 12½ and 9 per cent.

IV BACTERIAL FERTILIZERS.

The discovery of the mechanism of nitrification and the fixation of atmospheric nitrogen by the bacteria of root nodules, soon led to attempts to aid the process by the addition of nitrogen-fixing bacteria. In 1895 Nobbé and Hiltner patented a process of inoculating peas and beans and the soil in which they grow by soaking the seed with an infusion of a gelatin culture of the bacteria of the root nodules. Bayer offered a pure culture of Ellenbach's bacillus, mixed with potato meal, but Maerker soon concluded, from the contradictory results obtained, that the preparation had failed to prove its value In 1904 the United States Bureau of Agriculture distributed 12,000 boxes of bacterial cultures, which appear to have produced good results, in the majority of cases

But the effect of these preparations is uncertain, as the abrupt change of medium may avert the development of the bacteria. The soil naturally swarms with nitrifying bacteria, but their growth may be checked by various causes which will have the same effect on the few millions that are added

Stocklasa has endeavored to obtain hardier varieties by cultivating the bacteria in a large mass of earth, and has obtained remarkable results, but in view of the uncertainty mentioned above, it is prudent to defer judgment until several more years of experiment have elapsed

V THE VALUE AND THE FUTURE OF THE NEW FERTILIZERS

The value of the nitrogenous fertilizers obtained by artificial methods has been abundantly and decisively proved, but the same statement cannot be made in regard to the other new fertilizers every one of which has given contradictory results in the hands of different experimenters Similar uncertainties, however, attended the early experiments with other chemical fertilizers the value of which is now universally recognized We have learned how to use nutrient fertilizers and we shall learn how to use stimulants. And this knowledge will be productive of incalculable benefit to agriculture

## Charcot and the Antarctic.

Lest anyone should suppose that Dr Charcot went to the Antarctic largely for the purpose of reaching the pole it may be said at the outset that his chief object was one of scientific research only He only reached latitude 70 degrees, and therefore can hardly compare in achievement with his predecessors, and notably with Shackleton and Scott. What he did was to explore a region of archipelagoes and waterways, of which very little is known, and to broaden our knowledge of an ice barrier which extends westward from the South Shetland Islands unbroken

Although Dr Charcot returns with none of the laurels of Shackleton and Scott, his explorations will be of much assistance to future Antarctic explorers From the meager account of his findings it would seem that any attempt to approach the pole by way of the straits of the South Shetland Islands is doomed to failure, and that Commander Peary's plan of attacking the pole in a direction opposite to that pursued by Shackleton is hopeless. So far the only starting point that holds out any promise at all is the base of Ross's ice barrier, where the volcanoes Erebus and Terror are to be found Here and here only can an expedition winter not more than a few hundred miles from the pole

## The Current Supplement.

The current SUPPLEMENT, No 1782, contains some very striking illustrations of the Paris flood, which show to what extent the capital of France has suffered from the inundation. Mr H F Stimpson contributes an excellent article on efficiency in shop operations, in which he shows how shop efficiency can be increased, as well as some results secured by the methods which he advocates. Mr Claude Grahame-White, in an article "Some Experiences of an Aviator," sketches his own experience, and thus shows many an aspiring aviator what he has to avoid. Another paper on explosives for use in coal mines by Munroe and Hall is presented. The second and concluding installment of the article on the Wright injunction, containing extracts from the court's opinion and the briefs is published E P Buffet concludes his splendid biography of Leonardo da Vinci, in which he pays a tribute to that great man's engineering ability When the Nobel Prize was awarded to Mr. Marconi, he read a paper at Stockholm, in which he summarized the recent development of wireless telegraphy. That paper is published in the current SUPPLEMENT.

## An Injunction Against Paulhan.

Judge Hand, in an opinion filed in the United States Circuit Court, granted the injunction *pendente lite* asked for by the Wright Company against Louis Paulhan, the French aviator, alleged to be using in his exhibition flights here a machine which is an infringement of the patents granted to Orville and Wilbur Wright. This decision prohibits Mr Paulhan from using his machine in this country pending the trial of the Wrights' suit against him.

After discussing the prior discoveries cited by the defense, Judge Hand in conclusion says

"It is, of course, unusual to grant a preliminary injunction before any adjudication and without any acquiescence However, when the right is not seriously attacked, and when the infringement is clear, the court should not hesitate to interfere

"From the showing made I cannot doubt that the complainants first put into any practical form the system of three-rudder control. That there may be other systems is not the point, let the defendant use those if he will Nor is it necessary to conclude that the complainants were the first to fly Upon that I decide nothing whatever, for it is not an issue in the case.

"All I do say is that I cannot find that anyone prior to their patent had flown with the patented system, and that the changes from the specifications which the defendant had made are no more than equivalents which do not relieve from infringement.

"It is quite clear that for the complainants' protection a writ must go *pendente lite*, because the defendant, being a non resident, who is here transiently, there is no way in which they may insure themselves of the monopoly they have acquired except by preventing his use of it at once"

## A Library in the Sahara.

The French Colonel Gaden, who recently led an expedition into the southwestern region of the Sahara, found in the course of his investigation that one of the most powerful princes there, the Sheik Sidia, was the founder and possessor of a rather large library, a report of which is published in the latest number of the Revue du Monde Musulman This library is small, indeed, when measured by our ideas of such a foundation, for it contains only 683 books and 512 manuscripts Still it not only proves that a most urgent need of books has seized the most distant outpost of Mohammedan cultivation, but also provokes most lively interest in consequence of its composition

Approximately the books comprise thirty groups relating especially to koranic erudition the doctrine of faith, history, jurisprudence philology, travel and discovery, poetry and fiction, married life, magic recipes, interpretation of dreams and astrology The library, therefore, bears the impress of sheer orthodoxy, which is further manifested by its lack of books from forbidden provinces, such as philosophy and the natural sciences, but already the existence of printed books, the production of which is deemed a rigorous contradiction of the strict tenor of the Koran, proves that the revolution in the production of books, which began in Stamboul toward the end of the eighteenth century, has to-day acquired citizenship in the whole Islamitic world, and that at no remote day also in this circle of culture and of passionate political aspiration and achievement the printed book will force the written book into a very dim background Islam, long obstructed by crass ignorance of many foreign things among them books especially, which could have exercised a most beneficent influence on its daily life, is now quickened by the frequent book in its own tongues. which comes galloping from European publishers even into the precincts of its haughtiest orthodoxy The printed book is already an irresistible leaven in Islam.

## Death of Alfred Spear.

Alfred Spear of Passaic, N J., died at his home in his 87th year He was one of the first who ever conceived the idea of a moving sidewalk. His model interested such men as Peter Cooper, Horace Greeley, and several other prominent men The scheme had so much to commend it that two Legislatures, those of 1873 and 1874, authorized the use of his sidewalk, but the Governor of the State vetoed the bills.

## The Sensitiveness of the Telephone.

Preece has calculated that an audible sound is produced in a telephone by a current of 6 by $10^{-13}$ amperes, and Pellat has calculated that a sound is produced by a difference of potential between the two stations, amounting to only 1-2000 volt. These statements give some idea of the great sensitiveness of the modern telephone, but the sensitiveness of the human ear, which perceives the invisible vibration of the telephone diaphragm, is no less remarkable.

# Correspondence.

### HOW A TROLLEY CAR REVERSED ITS POSITION.

To the Editor of the SCIENTIFIC AMERICAN

On January 20th, 1910, about 12.40 P M, a curious and unique accident happened in regard to limited car No 230, D. and F, at the crossing of Main and Ash Streets, Piqua, Ohio. The phenomenon was so remarkable that I have concluded to make this report of it, and if you see fit you may lay it before your readers.

The car was headed south on Main Street, running perhaps ten or twelve miles per hour At the switch in Ash Street, where connection is made with the city line, the rear truck left the main line and followed the Ash Street line, and the car body turned completely end for end, returning almost completely to the main line. Neither truck was at any time off the rails and even the trolley wheel was still in working contact with the over-head wire when the car stopped The brake rod connections were all stripped and torn loose, also the wire connections from controllers to motors were severed No one was seriously injured, and a casual observer coming on the scene, as the writer did, a few minutes after the occurrence would not notice that anything out of the ordinary had transpired

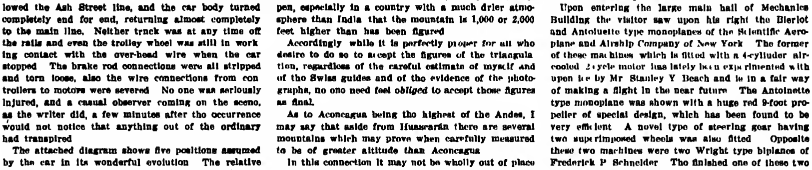
The attached diagram shows five positions assumed by the car in its wonderful evolution The relative position of the truck with reference to the body and also to the tracks is shown, the end of the truck normally positioned toward the center of the car body being indicated by *a* and *b* The end of the car headed south before the accident is indicated in each figure by *F*

Fig. 1 indicates the status of things when the truck *b* is about to turn from the main line. Figs. 2, 3, and 4 show intermediate positions, and Fig 5 the car when it came to rest

E. B RAYNER.

Piqua, Ohio.

[The mere momentum of the car would not account for the return of the car to the main line The fact that the trolley wheel remained on the line suggests that the motorman must have reversed the rear motor, which acted to push the car back in the reversed position to the main line.—ED.]



### MISS PECK REPLIES TO MRS. WORKMAN.

To the Editor of the SCIENTIFIC AMERICAN

Having observed in your issue of February 12th a letter in reference to the altitude of Mount Huascarán and my record from Mrs. Workman, may I state my own position a little more definitely?

After making the ascent of Mount Huascarán, north peak, September 2nd, 1908, of which I brought back absolute proof in the shape of photographs, I gave my reasons for believing the mountain to have an altitude of 24,000 feet, although on account of the high wind I had been unable to take hypsometric observations on the summit.

Naturally, I did not expect the scientific world or anyone else to regard my estimate as an exact measurement. If anyone did so, I cannot be responsible

It was, of course, quite within the province of any one to take so great an interest in the matter as to spend some thousands of dollars in sending engineers to Peru to make a triangulation of the mountain, and to publish this as the absolute height of Huascarán

There is, however, something to be said in regard to the accuracy of such triangulations. Permit me to quote from the recent work of Mr A. L. Mumm (of the English Alpine Club), "Five Months in the Himalayas"

"The results of triangulations do not always agree and even when they practically coincide, they cannot be accepted as absolutely unimpeachable There is good reason to suppose that the effect of refraction is not yet sufficiently understood for the allowances made for it to be perfectly accurate and the higher and more remote the summit, the larger is the possibility of error Bearing these facts in mind, it will be apparent that anyone who starts to form a decided opinion as to what persons are entitled to the honor of having reached the highest elevations has a very pretty tangle to unravel And I will leave it at that. Longstaff [who made the ascent of Trisul, 23,406 feet] lays no claim to any record, and goes out of the way like a good sportsman to establish the record of a predecessor"

Another disinterested authority is Dr. Norman J. Collie (also of the English Alpine Club), who has had much experience in the Himalayas and who stated to Prof H. C. Parker that the amount to be allowed for refraction on high snow mountains was most uncertain, that therefore the altitude of the great Himalayan peaks, though given in precise figures, was still in doubt

Furthermore, I once met a former member of the British Royal Engineers who told me that the triangulation of the well-known mountain K² recently attempted by the Duke of the Abruzzi, was made by a friend of his, whose allowance for refraction was double what he thought should have been made With the smaller allowance K² would be about 4 000 feet higher than it is now regarded

It is therefore obvious that if similar allowance for refraction is made on Huascarán, it may easily happen, especially in a country with a much drier atmosphere than India that the mountain is 1,000 or 2,000 feet higher than has been figured

Accordingly while it is perfectly proper for all who desire to do so to accept the figures of the triangulation, regardless of the careful estimate of myself and of the Swiss guides and of the evidence of the photographs, no one need feel *obliged* to accept those figures as final.

As to Aconcagua being the highest of the Andes, I may say that aside from Huascarán there are several mountains which may prove when carefully measured to be of greater altitude than Aconcagua

In this connection it may not be wholly out of place to say that while Mrs Fanny Bullock Workman has, according to the newspapers frequently announced her readiness to furnish evidence of the altitudes claimed by herself, when I wrote to her stating that I should be glad to see the figures of her observations, an interest shared by some other Alpinists she informed me that they had not been published in any of her writings, nor did she offer to give them to me personally

ANNIE S PECK.

New York, N Y

### The Aeronautic Show at Boston.

The first exhibition of aeroplanes, balloons, and aeronautic apparatus exclusively to be held in the United States was held in Mechanics Hall Boston, Mass, from the 16th to the 23rd instant This first Aeronautic Show, although fairly representative of the different experimenters, was somewhat of a disappointment in that there were no motor-driven heavier-than-air machines exhibited that have actually flown, while 50 per cent of the power machines were shown without motors This fact however, did not deter one from getting a good idea of the design and construction of the aeroplanes proper

The question of reliable light weight motors at a reasonable price is still a burning one, and a fortune awaits the man who will produce such motors—of 25 and 50 horse-power respectively—to supply them to aviators upon easy terms Eight different makes of motors were on exhibition, three of these (Curtiss, Cameron, and Harriman) being of the 4-cylinder 4 cycle type, two (Waterman and Duryea) of the 4-cylinder, 2-cycle type, and two (Easton Cordage Company and Buffum) of the 4-cycle, 8-cylinder and 12-cylinder V type respectively An Elbridge 3-cylinder water-cooled 2-cycle motor was also shown on the Wright type biplane of F P Schneider The 25-horse-power 4-cylinder Duryea motor which was shown upon the Blériot type monoplane of Stanley Y Beach, is air-cooled by means of thin copper strips wired to the cylinders. The Cameron motors—a 4 and a 6-cylinder of 30 and 45 horse-power respectively—are also air-cooled with the usual cast flanges The smaller of these two motors and the Duryea motor both weigh about 200 pounds, or approximately 50 pounds more than the Curtiss 25 30 water-cooled motor with radiator and water The reason for this apparent superiority of the water-cooled motor as regards weight is found in the fact that the Curtiss is a specially constructed aeronautic motor, whereas the air-cooled motors mentioned are simply automobile motors adapted to aeronautic use and not lightened nearly as much as it is possible to lighten them. The same may be said of the Elbridge, which is a marine motor The Waterman, another light marine motor built for canoes and dories, weighs just under 100 pounds complete with flywheel, which can be dispensed with, and develops about 15 horse-power The Harriman is a special 4-cylinder motor of 50 horse-power and weighs 200 pounds It has copper water jackets and aluminium crank-case The bore and stroke are 5 inches. The 8-cylinder V type motor has crank-case and cylinders cast of macadamite The cylinders are lined with cast iron and the pistons also are of a special grade of this metal The bore and stroke are each 4 inches. The output is 50 horse power at 1,200 revolutions per minute The 12-cylinder V-type Buffum motor is constructed similarly to the Easton each row of cylinders being cast in one piece with the upper part of the crank-case and afterward being bored and lined with cast iron This motor is beautifully finished Its weight complete is but 415 pounds, and an output of 100 horse power is claimed for it at 1 800 revolutions per minute

Upon entering the large main hall of Mechanics Building the visitor saw upon his right the Blériot and Antoinette type monoplanes of the Scientific Aeroplane and Airship Company of New York The former of these machines which is fitted with a 4-cylinder air-cooled 2-cycle motor has lately been experimented with upon ice by Mr Stanley Y Beach and is in a fair way of making a flight in the near future The Antoinette type monoplane was shown with a huge red 9-foot propeller of special design, which has been found to be very efficient A novel type of steering gear having two superimposed wheels was also fitted Opposite these two machines were two Wright type biplanes of Frederick P Schneider The finished one of these two machines had movable flaps upon the rear edges of the wings instead of the warping arrangement used by the Wrights.

Proceeding onward around the hall, the visitor next saw two new monoplanes—one (the Morock) a small demountable Blériot type machine having wings laced upon steel tubing and the other (the Burlingame) a large monoplane with trussed inclined struts running from the bottom of the wide central frame to the ends of the wings A 50-horse-power Harriman motor, direct-connected to a large and thick propeller, was placed at the front of this monoplane

A biplane that attracted considerable attention was that of Victor Page This had a rectangular central body and extremely thick wings with a deep curvature, A novel revolving cylinder 2-cycle motor (the L. A. W ) was pivoted in front, so the propeller mounted upon it could be directed upward or downward

The Hayward and Erickson biplanes were constructed entirely of bamboo In general outline they resembled the Curtiss, as did also the Elsner & Downey and the Reaud machines The Erickson biplane had a Buick automobile motor weighing 240 pounds fitted, the weight of the biplane alone being but 220 pounds

The finest piece of construction on exhibition was the Herring machine, built by the Starling Burgess Company, a well known boat building concern of Marblehead, Mass This machine, in general appearance resembling the Curtiss biplane was mounted upon three round skids no wheels being used The horizontal rudder was worked by the aviator's feet and the vertical rudder by hand A long inclined rod was placed on each side of the seat, to which the aviator can cling Springs were introduced in the guy wires, no turnbuckles being used The poles that carry the front and rear rudders were all hollow A Curtiss motor with a 4 bladed propeller of Mr Herring's design was fitted The machine complete weighed less than 400 pounds The propeller is said to give 260 pounds thrust, which, it is claimed, is ample to start the machine on any ground on its skids The stability device for lateral equilibrium was not exhibited

There were also several gliders on view, and a large number of models of all kinds, most of which were built by boys The exhibition as a whole was a very creditable one It leads one to believe that America will soon catch up to Europe in the aeronautic industry as it did with the automobile

Balloons were also in evidence Among them was the New England Aero Club's balloon in the very middle of the hall, inflated almost to its full capacity This balloon has made 45 ascensions and has traveled 1,251 miles Leo Stevens exhibited the basket of his 30-passenger 160 000 cubic foot balloon A huge hot-air balloon from which a trapeze performer made five parachute drops at Coney Island last summer is also to be seen.

# THE COCHIN FOREST RAILWAY

**BY EDWARD HARRAN**

The Cochin Forest Tramway is an interesting little line of tramway on the meter gage in the semi independent State of Cochin in South India It runs slightly to the north of the 10th parallel of latitude and to the east of the 75th parallel of longitude, and owes its origin to the fact that the forests of Cochin form one of the most valuable assets of the State, their approximate area being 505 square miles, or nearly one half of its entire extent Their commercial importance it is stated, was vaguely realised as far back as the beginning of last century, but the earlier attempts to work them were of the usual spasmodic and unsystematic nature which characterized original efforts in forestry throughout the Indian peninsula. In the year 1835, however, a regular forest department, under the control of a European officer, was formed and worked for some sixty years on old fashioned lines Though the department throughout this period brought in a certain amount of revenue to the fact that a land route, provided means of transportation over it were available, would tap a far richer forest area than a proposed river route alone, while, of course, it would be open all the year round. So it came about that the idea of a tramway in three sections arose, was recommended to and sanctioned by the Durbar The first section was to cover a distance of 8 miles in the valley, to be followed by a self-acting inclined tramway 5,000 feet long. The second section, 4½ miles long, was to be followed by a slide 7,000 feet long, whence the third section, also 4½ miles long, was to extend to the Kurumali River, from which point timber could be floated to the railway station at Trichur during the monsoonal period and carted to the Chalakudi Station in the dry weather According to this first propounded scheme, timber from the hitherto unworked Parambikolam Forest was to have been floated by the Parambikolam River to the tramway terminus in the valley A visit paid by his logs both at the head and floor of the slide proved expensive. To remedy this latter, the conversion of the slide into another self-acting incline was decided upon. To remedy the first, Mr Alwar Chetty recommended, and the Durbar sanctioned, another extension of the tramway, one of 15 miles to Chalakudi, to meet the Shoranut-Cochin Railway at that station, a connection, with the acquiescence of the Madras Railway authorities, being made between the railway and tramway there.

To-day the total length of the line as it stands completed at the time of writing is 49½ miles divided into three sections. The first section extends from mile 1 to 21, the second from mile 23¼ to 27, and the third from mile 28 to 49½ The first and second sections are connected by a self-acting wire rope manipulated double way of 1½ miles, while the second and third sections are similarly connected by another incline a mile in length

The logging locomotive, truck, and caboose.

Stone-and-timber bridge on the line of the Cochin Forest Railway.

Elephants moving logs for shipment.

A train of timber cars. Note the density of the forest growth.

THE COCHIN FOREST RAILWAY

State, there was little or no pretense made of administrating the forests on scientific principles, with the more or less natural result that while the interior of the forest area (from which there were no facilities for transporting the cut timber) remained practically untouched, work being confined to the more accessible portions and those from which transport was easy It was not until the year 1895 that a move for the better was made when suggestions were made by the Resident, Sir James Thomson, which culminated, early in 1897, in the Madras government placing at the disposal of the Cochin State a British forest officer, Mr Foulkes, for the purpose of inspecting the forests and formulating proposals for their better and more profitable administration This gentleman's report included the recommendation that the services of a trained and experienced forest officer be obtained, and, acting in accordance with this suggestion, the Cochin Durbar obtained from the Madras government the loan of Mr V Alwar Chetty T F S for a period of seven years. His first care was to inaugurate a period of rest for the overworked area of timber and to set about securing a suitable outlet for the prospective output of the then virgin forests. Surveys disclosed the Highness the Maharaja of Cochin to the Parambikolam and Nelliampatty forests in October, 1903, suggested a revision of this scheme which provided for the extension of the proposed tramway to Parambikolam, an additional 12½ miles, the experience gained during the preceding year or two having shown conclusively that the Parambikolam River could not be relied upon to carry every year anything like a year's full yield of timber A survey of this extension was made by Mr Haldwell, a specially engaged engineer, in 1904

According to the original scheme, the traction of the timber trucks was to have been by manual labor, but when the length of the proposed line amounted to 31 miles, it was recognized that manual labor would prove both too expensive and too laborious, and in September, 1904, locomotive engine traction was finally decided upon The modifications of the original scheme already alluded to necessitated a full reconsideration of other portions of it, chiefly the proposed combined river and road transport which it was anticipated would not clear the accumulations of timber Also in practical working it was found that a timber slide, especially in the case of lengthy and heavy logs, was unsatisfactory, and the handling of

Throughout its whole length the Cochin Forest State Railway is excellently constructed. The gage is 1 meter; the average gradient of the line 1 in 80 and the maximum gradient 1 in 2.5 which gradient occurs on the third of the five inclines which have been embodied in the construction

The inclined ways are so constructed as to be self-acting, and three of them are situated in series between 21 and 23 miles and the other two between 26½ and 28¾ miles. They are worked by means of wire cables controlled from brake houses by gear brakes independent of each other, and consisting of horizontal wheels round which the cables pass two or three times. The inclines are double railed with suitable cross-over points at the up-hill side of each brake house. The points are so arranged that a descending load, which travels down by force of gravity, requires practically no up-hill shunting, the locomotive places the truck, which on being uncoupled is then ready for the descent. In some cases, however, empty trucks going up have to be hand-shunted after being placed, in order to place them on the side of the upper incline on which the traction rope lies. The ropes are flexible and are of 1½ inch plow steel wire. The [illegible]

passes over a grooved pulley 4 feet diameter, after which it forms a figure 8 over a loose pulley back again over another 6 foot pulley mounted on the same shaft as the first and thence to the other line

On the vertical shaft on which these two pulleys are, and on which the rope binds are mounted two hori zontal drum pulleys each 6 feet diameter 2½ inches broad with ¼ inch flanges Steel hand brakes 3/16 inch thick and 8 inches broad studded with hard wood brake blocks 6 inches long can be applied to these drums by powerful linked levers controlled by hand wheels and screws, to control the speed of the load descending the incline The grooved pulleys round which the rope binds are filled in with leather sections on end grain to give a good grip The cast iron portion of these wheels is suitably dovetailed out to contain the leather packing

The first second and fourth of the five inclined ways are on curves round which curves the wire ropes are guided by vertical rollers On the straight portion of the inclines the cable is supported by horizontal rollers placed 30 feet apart Illustrations of one of these inclines are here reproduced The rolling stock of the Cochin Forest Railway consists solely of open trucks specially designed for carrying timber with swiveled bolsters and chilled cast-iron wheels

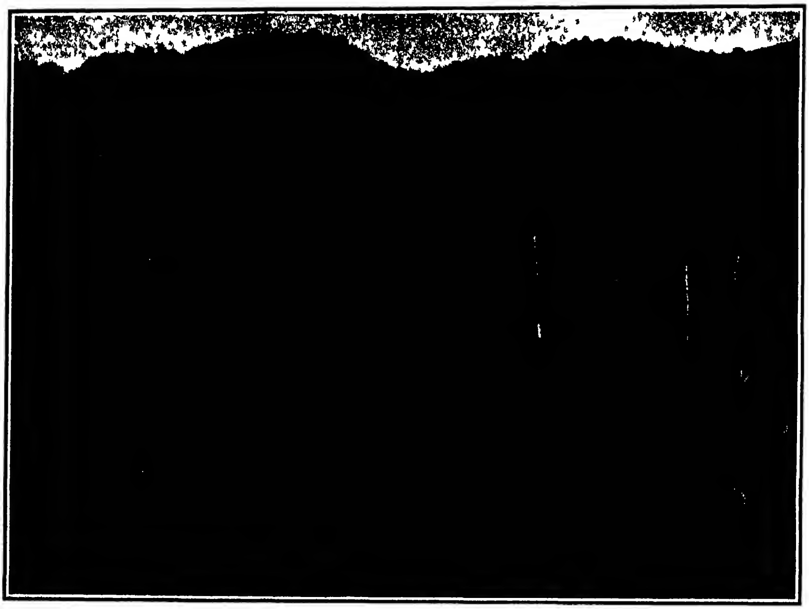
### The Art of the Cave-Dweller.

A very noteworthy discovery of caves which has brought to light a number of art objects of the oldest inhabitants is reported by Prof Moser in a late num ber of Umschau In a depression which has the ap pearance of a trough of the valley extending from the Karst (Australian) plateau Trieste Nabressina Duino, to the Volnik Mountains are found numerous caves to which leads a gate of rock under the project ing wall of the cliff Their interiors are rooms small or spacious, which were first only places of sojourn for the Karst cave-dwellers who originally nomads later settled down to habitual residence in them That the caves have served a long time as abodes is proven by the fact that in them are found frequent very thick layers of clay interstratified twice, thrice four times, with ashes. In the latter are relics of the household Among the caves visited the Rothgart cave, situated near the viaduct of the Southern Rail way, near Nabressina, was subjected to the most per sistent examination Prof Moser has yet made In this cave were found four such layers of clay separ ated by layers of ashes While relics of the new stone-age were found in the first and second layer of ashes in the third and fourth layers were discovered remains of the painter s mussel land snails the bony scales of the swamp-turtle and a mammal fauna such as the otter beaver goat stag and wild bear which manifestly point to the fact that the first cave-dwell ers resorted to the fresh water districts for their sus tenance while the later cave-dwellers found a much more generous source of nourishment along the coast An important fact is the presence in those oldest lay ers of frequent tools and to the same layers belong the especially interesting art objects engravings on animal bone described pictorially many of them in the Professor s report. On a polished piece of stag s horn for instance may be seen the rud ly made draw ing of a human figure that stands between two tree-trunks showing many branches As in the s t draw ings of children the head is represent d by a round depression and hands and feet by slits slightly curved On a second engraved piece of bone a jawbone that was found in the third layer of ashes is pictured with a contour of almost straight lines a wild boar of which the head is almost triangular the tusks being clearly drawn the eyes and ears being faintly indicated the bristles on its back appearing with per fect distinctness and the curl in its tail being rather indistinct That the artist of the cave sought to re produce the aspect of nature in which he had often seen and slain the wild boar is shown by the high grass in which the animal stands and which is repre sented by strong incisions. On a thigh bone is easily recognized the head of a sea turtle with eye and deep ly cleft mouth the scales and folds of the skin are indicated by easy strokes and above the head is a sufficient hint of a fluttering dragon fly and not far from it are tufts of reed The two last engraved pieces of bone the Professor attributes to an early settlement in the new stone-age while the awkward portrayal of the man may be considered as derived from the old stone-age

While the layers of ashes contained a generous num ber of finely worked tools of bone and pieces of orna ment, the occurrence of relics of man himself is re stricted to two skeletons with additions from the Moser cave and very recently the Professor found a well preserved human lower jawbone in the so-called Cave of the Bears Sandstones marked with grooves made by whetting the bone tools on them prove that the caves were also the workshops of the cave-dwell ers A high degree of development is shown by the pottery the vessels formed by a free hand are mani fold not only in their form and material but also in their decoration one piece being marked with a broad spiral band immediately on either side of which the depressions of the vessels are filled with white color in which are the ears of corn and leaves of palm which ornament the band This piece almost reminds one of the decoration of Mycenæan pottery

### Have Fishes Memory?

Studies as to the mental powers of animals have already been made on several occasions but only re cently have inquiries been made as to whether fishes have a memory or not Results have shown traces of a m mory both in coral zoophyt s and oth er d llers of the d e[illegible] Experiments have been made with sev eral fishes b it the most striking results have been ob tained with the gray p rch which lives hi dy on a small silvery hued sardine Some of these were taken and colored red and were then put into th tank where the perch was with several oth r silver colored sar dines Of course th normal ones were at on e at tacked and eaten but it was not till hungry that the perch made a tentative meal of one of the r d ol red victims on recognizing the sar lin flav r however he promptly demolish d th r mainder S ubsequently the specimens in the tank devour d the sardines irre spective of color thus showing not only tra es of a mem ry but also the power to differentiate color Sub sequently sardines colored red and blue were pla ed in the tank together with the silver on s th same scene was repeated the blue ones not being atta ked till the others were eaten and hunger compelled in vestigation of the new comers After this introduc tion the perch ate the sardines of all thr e typ s with out any difficulty Some spines of the sea n ttl (ac tinia) were then fastened to the blue sardines these were at once avoided by the perch who promptly got out of the way of the new comers This showed traces of memory as the results of contact with the sea net tle were clearly shown and recognized



Part of the main line with empty train on a grade

THE COCHIN FOREST RAILWAY

# THE NEWLY DISCOVERED GOBLIN SHARK OF JAPAN

BY DR. L. HUSSAKOF

Every now and then the zoological world is startled by the announcement of the discovery in Japanese waters of some very rare or very ancient type of animal. So often is this the case that zoologists have come to look upon the deep waters of Japan as a sort of naturalists' wonder realm—a preserve in which live all manner of interesting animals, some of them of an archaic type long extinct in other parts of the world. The expectation of remarkable discoveries in these waters is so strong that I have heard a distinguished American zoologist, who is himself well acquainted with Japanese waters, say that he would not be greatly surprised to hear some day that a real Mosasaur or Ichthyosaur had been hooked in the depths of *Kuro Shiwo* or warm Black Current of Japan.

It is in these waters that Japanese fishermen occasionally take on their lines a shark whose grotesqueness has won him among natives the name of *Tenguzame* or goblin shark. One of these "goblins" came into the hands of President David Starr Jordan of Leland Stanford University a dozen years ago and was at once recognized as an interesting archaic type whose close relatives had long since become extinct. President Jordan described it under the name of *Mitsukurina owstoni*—the name being given to honor at the same time the late Prof. Kakichi Mitsukuri, who for a quarter of a century was the leading light of Japanese zoology, and Mr. Alan Owston, a natural history dealer of Yokohama, who was instrumental in securing the specimen. This name, by the way, does not stand at the present day but must be replaced by *Scapanorhynchus*—a name which had previously been applied to the teeth of the extinct species of this type of shark found in the rocks of the Chalk period, in different parts of the world. In accordance with scientific usage, therefore, the Japanese shark described by President Jordan must now be known as *Scapanorhynchus owstoni*.

It is now to be recorded that a second species of goblin shark has turned up in a most unexpected way. It happened thus. All of the sharks caught in Japan in the past years and sent to the various museums — about twenty in all—were looked upon as belonging to the same species, *S. owstoni*. No one had ever thought of comparing several specimens; in fact, these sharks are so rare in museums that comparison is generally quite out of the question. It was therefore a pleasure for the writer to have had the opportunity of comparing several specimens in the collections at Columbia University and the American Museum of Natural History and to find among them a new species of the goblin shark. This has recently been described in the Bulletin of the American Museum of Natural History as *Scapanorhynchus jordani*—the specific name being given in honor of President Jordan, our greatest authority on the fish of Japan.

Now to come to the fish himself. As seen in the illustration (Fig. 1) the new shark is certainly grotesque, well deserving his sobriquet "goblin." The largest specimen in this country is one in the National Museum at Washington, measuring over eleven feet, and the species probably attains a length of fifteen. Fortunately it is not given to frequenting the bathing-beach, but keeps to deeper waters—usually about fifty fathoms. As is generally the case with fish from deeper water, this shark is soft and pliable. Even after hardening in a preservative for several months, it can be rolled into a ball. The most remarkable feature is the curiously elongated "nose" (shown in Fig. 2). It is this, together with its protruding jaw and small beady eyes, that gives the shark that ugly appearance. The teeth (Fig. 3) are sharp and slender, each like the pointed end of an awl. They constitute a most effective weapon, which must be fingered with discretion even on the laboratory table. As to the peculiar anatomical characters, suffice it to say that in the total make-up it is so different from all other sharks that President Jordan was at first inclined to classify the genus to which it belongs in a special family by itself.

As to the differences between the new species and the one already known, we need say only a few words.

**Fig. 1.—The newly discovered goblin shark (Scapanorhynchus Jordani).**

The pictures show the differences at a glance even to the layman in matters ichthyological. The new form (lower picture) is distinguished by a much less protruding jaw, by a very much smaller spiracle (the minute accessory gill pore seen at some distance back of the eye), and by the fact that the eye is situated opposite the middle of the jaw instead of back of it. These features are quite sufficient, in the opinion of experts, for separating our goblin as a distinct "kind." To the general reader they may perhaps be of interest as examples of the degrees of difference which are used by specialists to distinguish species of fish.

**Fig. 3.—Under side of head of Jordan's goblin shark, showing mouth and teeth.**

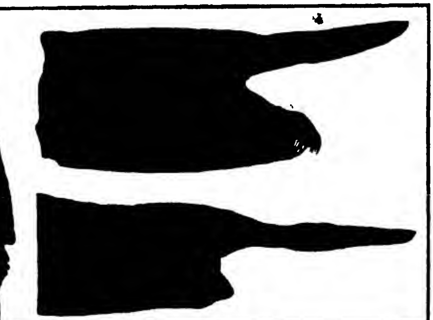


**Fig. 2.—Heads of two species of goblin shark. The lower one is that of the newly discovered Jordan's goblin shark (Scapanorhynchus jordani).**

**THE NEWLY DISCOVERED GOBLIN SHARK OF JAPAN.**

---

**Pipe, Cigarette, and Cigar.**

The question as to which of the three forms of smoking, the pipe, the cigarette, or the cigar, introduces the greatest proportion of nicotine into the smoker's system has never obtained a completely decisive answer, although it has received considerable discussion from time to time. At one time it was freely asserted that the tobacco which contained the highest amount of nicotine necessarily tended to be the most injurious, no matter in what form it was smoked, but we now know that the form of smoking plays an important part. There was a theory that not in all three cases was the original nicotine in the tobacco conveyed as such to the mouth, sometimes it was destroyed by effective combustion, while at other times pyridine was responsible for toxic effects. According to this theory, which was all on the right track, the cigarette was least harmful, because the tobacco along the thin paper wrapper was exposed freely to the air, and as a consequence the tobacco was well burnt and all nicotine was destroyed. Against this it was held that in such a case one poison disappeared only for another one to be elaborated, and carbon monoxide was found in marked quantity as a poisonous constituent of cigarette smoke. As a matter of fact, carbon monoxide is invariably found in all tobacco smoke, and that circumstance should be sufficient to warn all smokers against inhaling it persistently. Theories as to what happens in the combustion of tobacco in the various ways it is smoked next took into account the extent to which condensation products were formed and retained in the tobacco. The most effective condenser, of course, is the pipe, and there can be little doubt that owing to the length of the stem a comparatively small proportion of these condensation products reaches the mouth. In the cigar, on the contrary, the condensing process has a tendency to travel throughout the cigar, at all events, as the cigar gets shorter the condensed product area gradually reaches the mouth and eventually the products are conveyed there by the heat of the burning end. It has been said by connoisseurs that no cigar is worth smoking after one-half of it has been consumed, which seems to be a practical realization of theoretical considerations very suitable for application by millionaires. Again, a cigar that has been partially smoked and then allowed to go out is decidedly unpleasant when re-lit, owing doubtless to the spread of condensation products to the mouth end. In the case of the pipe, the burning area is always in the same place, it never comes near the mouth, and therefore the probability is that the condensation products do not reach the mouth in, at any rate, appreciable quantities. In the cigarette the condensation products eventually reach the mouth, but there is in this case less chance of condensation products forming since the combustion is unhampered, the tobacco being freely in contact with the air. The question of moisture, however, must not be left out in these considerations, for it is obvious that damp tobacco will form condensation products more readily than dry tobacco. It is probable, therefore, that a dry cigar or cigarette gives off less poisonous products than a damp one does, but not everyone smokes from choice a new cigar or an old cigarette. It is reasonable to conclude that the amount of nicotine reaching the mouth does not necessarily depend on the amount in the tobacco, but on the form in which it is smoked. In drawing this conclusion regard must, of course, be had to the quantity of tobacco smoked, but if the conclusion is correct, the pipe would come first as the least harmful form of tobacco smoking, then the cigarette, and lastly the cigar.—Lancet.

---

It has often been remarked that the centers of seismic and volcanic activity move slowly westward. In a recent issue of the Physikalische Zeitschrift, H. Wehner adopts this belief and endeavors to explain the westward movement by reviving the old hypothesis of a solid nucleus, separated by a thin stratum of liquid from the earth's crust, and rotating slightly less rapidly than the latter. According to Wehner's calculations, the nucleus makes a complete revolution, relatively to the surface of the earth, in 952 years. (There is room for a good deal of uncertainty in such calculations.) Wehner supposes, further, that the nucleus is studded with protuberances which are centers of activity and that these protuberances, coming into contact with weak parts of the earth's crust, cause earthquakes and volcanic eruptions. From this theory and the records of earthquake shocks observed by navigators of the Atlantic Ocean during the last sixty years, Wehner concludes that a group of these formidable protuberances has now arrived under the region between 1 deg. N. and 1 deg. S. latitude and 37 and 43 deg. W. longitude, and that danger is imminent in that part of the world,

# Patent Department

### FIREPROOF ARCH.

Pictured in the accompanying engraving is an arch used more particularly in fireproof work, which is of very simple construction It consists of but two tile sections, each provided with an air space usually designated as a "vacuum." The usual I-beams be-

FIREPROOF ARCH

tween which the arch is formed are indicated at *A* and *B* Each arch member comprises a top panel *C*, a bottom panel *D* and a side panel *E* thus giving the member the general shape of a wedge At the point of the wedge one of the members is provided with a tongue *F*, while the other member is formed with a groove adapted to receive this tongue When the two sections are fitted between the I beams they are thus interlocked A weight placed on the interlocked tiles produces an outward spreading thrust against the two I beams *A* and *B* To resist this thrust the I beams are braced by means of cross rods, as indicated by dotted lines in the illustration Our illustration shows part of the upper panel of one of the sections broken away to reveal the reinforcing which, in this case, consists of a netting of heavy iron or steel wire imbedded within the material The lower panel is braced by means of bars *G* imbedded therein which extend up into the tongue *F* They take the end thrust and materially strengthen this portion of the arch The "vacuums" or wedge-shaped air spaces formed between the panels serve to prevent undue travel of heat through the arch in case of fire A building having a large proportion of such arches is therefore to that extent rendered more nearly fireproof than would otherwise be the case The inventor of this arch is Mr Eugene F Fitzpatrick, of 153 Withers Street, Brooklyn, N Y

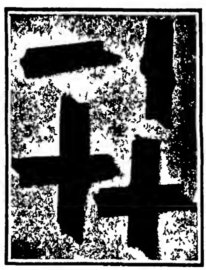
### MUFFLER FOR TELEPHONE TRANSMITTERS.

Unless one is using the telephone in a booth or in a quiet room it is impossible for him to exclude all local disturbing noises by stopping the ear that is not applied to the receiver, for the reason that the noises reach him by way of the transmitter of his own instrument In order to eliminate all such disturbing sounds a very simple device has recently been invented which may be applied to any telephone transmitter This device is illustrated in the accompanying engraving It is extremely simple, consisting of two members hinged together, one of them being a ring-shaped plate adapted to be placed over the mouth of the transmitter and provided with ears which are bent back over the outside of the transmitter A wire band is then fitted over the ears, and the latter are bent upward and hooked over the wire Owing to the outwardly flaring form of the transmitter the device is thus firmly made fast. Between the ring-shaped plate and the transmitter is a strip of felt which serves to prevent vibrations that strike the plate from being communicated to the mouthpiece of the transmitter The second member, which is hinged to the plate, is in the form of a flat cover provided on the inside with a lining of felt so that when it is closed down upon the other member it will exclude all sound from the transmitter The hinged cover is provided with a finger piece, by which it may be opened whenever one desires to use the transmitter but at all other times it should be closed to exclude local noises The inventor of this simple attachment for telephone transmitters is William D Plumb, 2022 Lexington Avenue, New York city

MUFFLER FOR TELEPHONE TRANSMITTERS.

### WROUGHT-STEEL SASHES.

In this the sanitary age we have come to recognize the importance of daylight in our work rooms as well as in our homes The germicidal effect of sun light is well recognized Add to this the fact that artificial light costs money, while sunlight is free, and nothing further need be said to demonstrate the superiority of the daylight shop, both from the sanitary and the economical point of view Recently a new type of window sash has been devised for industrial buildings, which, it is claimed, by doing away with the cumbersome frames and heavy mullions makes it possible to deliver 35 per cent more light through a given opening than heretofore The sash is of very simple construction, and yet is much stronger than the common wooden sash It is better able to with stand the pressure of the wind, and furnishes no fuel to a fire It is made of steel bars rolled to the cross section shown in the accompanying engraving The method of joining these bars is very ingenious and decidedly unique A small cross slot is made in the

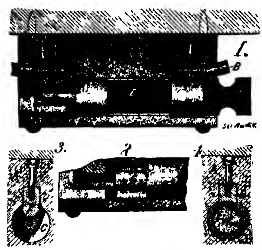


NOVEL JOINT FOR WROUGHT-STEEL SASHES.

vertical bar (Fig. 2) of the sash just large enough to admit the flange of the horizontal bar The molded part of the vertical bar is then pressed out so as to fold closely around the molded portion of the horizontal bar, as shown in Fig 3 In the latter bar a small notch is cut as indicated in Fig 1 to act as a lock It will be observed that the amount of metal removed in making this joint is infinitesimal The bars run without break from top to bottom of the window as well as from side to side, making a particularly strong framework, and this permits of using a much lighter section than is possible with a miter joint construction, so that a great saving is effected in the weight of the material used and consequently in the ultimate cost of the sash Furthermore, the unusual type of joint makes a break in the monotony of the window sash which is pleasing to the eye A patent on this type of sash has been secured by the Detroit Steel Products Company of Detroit, Mich.

### SAFETY FUSE BLOCK.

Heretofore when fuses such as the screw plug, ordinary cartridge, or the open wire type, have been used, it has been customary in making temporary installations, requiring a larger capacity than supplied by the block used in the original installation to remove the original fuse, and to substitute therefor one of larger and in many instances of a dangerously large carrying capacity This has resulted in permitting a load to be introduced on the wires which has taxed and in some cases broken down the insulation by heat, resulting often in producing a dangerous fire To obviate such possibilities the fuse block illustrated in the accompanying engraving has been devised It is so arranged as to prevent the introduction between the terminals of a line of a fuse having a larger carrying capacity than is designed for the line The block *A* as shown in Fig. 1 is provided with a cylindrical compartment that opens at one end into a recess *B* and at the other end communicates through a partition *I* with a recess *C*. Each recess is fitted with a lug adapted to receive the terminal wires of the line The lugs are engaged by screws that pass through the blocks and serve as binding posts to hold the line wires The lug *D* in the recess *B* is provided with spring clips of accurate form adapted to grasp the body of the fuse *E* The lug *F* in the opposite recess is also provided with

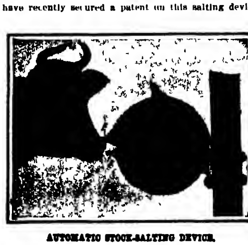


SAFETY FUSE BLOCK

spring clips adapted to engage a boss *G* which projects from the end of the fuse The fuse is provided with the usual metallic contact bands and one end is furnished with a handle *H* All of the fuses adapted to be used with a block of a certain ampere carrying capacity are fitted with bosses of the same size A fuse of larger carrying capacity however, would have a boss of larger diameter If one should attempt to insert a fuse of larger carrying capacity into the block the boss would fail to pass through the partition *I* and enter the clip *F* as shown in Fig 2 and no contact would be made with the line terminals The inventors of this electrical fuse block are Messrs. A A Moffit and G E Andrews, of 40 Bridgham Street, Providence R I

### AUTOMATIC STOCK SALTING DEVICE.

Cattle when housed or running free in a field need a limited supply of salt to maintain them in good condition If the salt is placed in troughs mixed with feed some of the animals will prevent others from getting a proper amount of the salt The accompanying engraving illustrates a device which affords free access to the stock for obtaining the requisite amount of salt and at the same time protects the salt from the elements and prevents waste It consists of a cup-shaped receptacle which is hemispherical, as indicated at *A* in the illustration A cover piece *B* is secured to the receptacle *A* by means of screws which are threaded into lugs *C* formed on the member *B* The cover piece is also hemispherical in shape, but is cut away at the forward side to admit the muzzle of the animal A hood *D* is hinged to the cover *B* and serves normally to close the opening in the latter At the forward side of the hood is a lip *E* which projects forward and is curved upward The receptacle *A* is provided with a similar lip *F*, which however is curved downward thus leaving an opening which will expose the salt and attract the stock In use a sufficient number of the salt holders are placed in the corral or the field where the stock range to enable the cattle to obtain the salt The animal raises the hood by shoving his muzzle beneath the lip *E* and rocking the hood back until it engages a lug *G* When the animal withdraws his muzzle for the salt holder the hood will close by gravity thus protecting the salt from exposure to the elements Messrs Frank and Thomas L. Pelfer of Benson Ill (R F D No 3) have recently secured a patent on this salting device



AUTOMATIC STOCK-SALTING DEVICE.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

BELT ATTACHMENT.—E. E. NYE, Groton, N. Y. The object in this case is to provide an attachment for holding the buckle end of the belt from slipping on the trousers. Use is made of a hook adapted to engage the fastening device for connecting the front flaps of the trousers with each other, the shank of the hook terminating in a pin adapted to be fastened to the belt.

### Of Interest to Farmers.

GATE.—J. W. MATTHEWS, Brady, Tex. This invention is an improvement on the former patent granted to Mr. Matthews, and provides a durable farm gate which can be opened and shut from pedals remote from the gate itself. It is positive in operation and requires the expenditure of little effort to close or open it, the gate being operable, for example, by the occupant of a vehicle.

MILKING MACHINE.—B. J. BIGELOW, La Crosse, Wis. An object of this inventor is to provide a machine which is capable of milking cows or other animals quickly and with little effort. The device will effect the operation in a sanitary manner, thereby preventing the spread of disease which is likely to result from the unsanitary methods of the ordinary process.

### Of General Interest.

ARTIFICIAL FUEL AND PROCESS FOR MAKING THE SAME.—C. F. BONNACK, New York, N. Y. This invention relates to artificial fuel, and particularly to fuels of this kind which are formed from small sizes of coal or from coal dust which is incorporated with a binder so as to form lumps or briquets which can be conveniently burned upon a grate.

PAINT AND VARNISH REMOVER.—M. HAXE, New York, N. Y. The improvement has reference to means for removing paint and varnish from woodwork and the like, and the object of the inventor is to produce a preparation which will operate effectively to soften the varnish and paint so as to facilitate its removal as suggested.

### Prime Movers and Their Accessories.

STARTING AND STOPPING DEVICE FOR GAS AND OTHER ENGINES.—J. W. ELLIS, Denison, Tex. This device for gas and other engines is for use in connection with a water supply system to provide a constant supply of water, and designed to dispense with attention except at long intervals. When the water falls below the predetermined level a switch is operated to close the main circuit which includes the storage battery and the motor, and as the current strengthens the rheostat is gradually cut out. The motor drives the engine, and when the latter attains its full speed the clutch is operated to connect it with the pump and the motor is converted into a generator, recharging the storage battery.

### Designs.

DESIGN FOR A PLATE OR SIMILAR ARTICLE.—A. KOHN, Weiden, Bavaria, Germany. The plate is round. The outer edge and bottom of the rim are circled by a narrow band comprising leaves and berries of very small size, producing a refined ornamental effect.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## NEW BOOKS, ETC.

THE FOURTH DIMENSION SIMPLY EXPLAINED. A collection of popular essays and editorial notes by Henry P. Manning, Ph.D., Associate Professor of Mathematics in Brown University. Illustrated. New York: Munn & Co., Inc., 1910. 12mo.; 251 pp. Price, $1.50 net.

When the Scientific American's Prize Fourth Dimension Competition closed, the judges were astonished at the number and variety of the essays which were received. For the most part the authors showed an excellent grasp of a very abstruse subject. Some of the essays were of such merit that to preserve them in permanent form seemed advisable. Accordingly Professor Henry P. Manning, who was one of the judges in the competition, was entrusted with the task of selecting about twenty of the best essays, supplying them with critical notes, and furnishing an introduction. The present volume is the outcome of his labors. The volume contains not only the essays which he selected, but also the essay of Lieut.-Colonel Graham Denby Fitch, which received the Five Hundred Dollar Prize, and the three honorably mentioned essays which were published in the Scientific American, together with his.

Professor Manning in his introduction dispels the notion that the fourth dimension is a mathematical delusion with which no sane man ought to occupy himself. He points out that the mathematician is not concerned with the existence or non-existence of the fourth dimension. He is simply concerned in the construction of a geometry in which there is no contradiction, nor anything that is philosophically impossible.

The essays in this book are all non-mathematical or popular in their treatment. They are therefore necessarily limited in their form of presentation. By a comparison of the lower dimensional geometries the essayists derive analogies for the geometry of four dimensions, analogies so complete that the subject can be very fully explained in a non-mathematical way. The analogies are a guide even to the mathematician, but the fourth dimensional geometry does not depend upon these analogies. As a system of theorems and proofs it is built up from its axioms by a process of logical reasoning just as the lower geometries are built up.

Each of the twenty-two essays in this book is 2,500 words in length. The reading of one essay does not involve the reading of the entire work, yet the entire book gives a very good view of what the layman wishes to know about the fourth dimension. No abstract mathematics can be found anywhere in the volume. The essayists have endeavored to explain the fourth dimension both by imagining the effect of transporting an ordinary third dimensional human being into fourth dimensional space, and also by explaining a third-dimensional man's possibilities in one of two-dimensional space. The result is a collection of essays which are as interesting as any fairy tale.

Manure spreaders, drill attachment for, C. H. Ellis ... 949,173
Massage apparatus, M. A. Haines ... 949,290
Massage apparatus, J. Salatino ... 949,360
Match box holder, H. C. Kirk, Jr. ... 949,186
Match case, H. Epstein ... 949,528
Match receptacle, cigar cutting, J. P. Crosthwait ... 949,521
Matchsafe, J. L. Dunning ... 949,223
Measurement gage, outside or inside, C. E. Johansson ... 949,276
Measuring device, foot, J. H. Waite ... 949,249
Meat compound, preparing a preserved, H. Toth ... 949,336
Meat press, E. M. Johnson ... 949,234
Meat slicer and cutter combined, J. Winkelmeyer ... 949,344
Medical implement, M. J. Rogers ... 949,392
Metals from solutions, electrolytic apparatus for recovering, W. A. Hendryx ... 949,016
Meter testing device, H. P. Westcott ... 949,040
Milk and cream purifying apparatus, J. H. Curran ... 949,205
Mill. See Cutting mill.
Minerals, separation of combined, A. S. Ramage ... 949,002
Miter box, W. Turner ... 949,109
Mixing machine, P. A. Koehring ... 948,996
Mixing machine, A. J. Cropp ... 949,098
Mold, J. A. Rathbone ... 949,496
Mold filling machine, J. Anderson ... 949,743
Molding apparatus, J. A. Rathbone ... 949,407
Mop, J. D. Keeney ... 949,079
Mosquito bar support, A. F. Chastant ... 949,620
Motor control, single-phase, E. F. W. Alexanderson ... 949,346
Motor control system, E. W. Stull ... 949,007
Motor control system, electric, W. Cooper ... 949,114
Motors and receptacles, support for, J. H. Neuschwander ... 949,197
Mount trimming machine, C. H. Cadieu ... 949,110
Musical instruments, valve for pneumatic, G. S. Williams ... 949,250
Muzzle and calf weaner, W. H. Lyman ... 949,730
Nail or spike puller, G. W. Trogner ... 949,137
Necktie, C. Reynolds ... 949,393
Nest for poultry, recording, G. A. L. Argles ... 949,610
Nozzle, J. G. Maslin ... 949,189
Nursing attachment, H. B. Cunningham ... 949,414
Nut lock, H. Beta ... 949,412
Nut lock, Davidson & Mauldin ... 949,624
Nut lock, C. H. Loehr ... 949,741
Oil burner, P. H. Herriff ... 949,079
Oil burner, Cowan & Felten ... 949,648
Oil burner, crude, F. D. Stafford ... 949,141
Oil gun, Molinari & Laurent ... 949,193
Open hearth furnace, S. E. Meyers ... 949,192
Ore sampling apparatus, A. J. McCone ... 949,284
Ore separator, G. W. Kaukel ... 949,709
Ores, nodulizing fine, J. Weatherby, Jr. ... 949,367
Oscillating motor, G. Hager ... 949,373
Pan, P. C. Howland ... 948,994
Pan and plate lifter, G. L. Degner ... 949,680
Pan lifter, D. G. & A. E. Henry ... 949,573
Paper bag machine, W. C. Fuller ... 949,468, 949,469
Paper bottle, C. F. Jenkins ... 949,036
Partitions, sanitary base for, G. L. Mason ... 949,380
Paste tube, F. Muller ... 949,545
Pen, fountain, W. E. Geyer ... 949,430
Pencil holder, J. W. Mills ... 949,091
Pencil sharpener, D. L. McBride ... 949,085
Photographic printing frame, D. J. Lindsay ... 949,125
Pianos, action for pneumatic player, Berglund & Webb ... 949,612
Piling metal, J. J. Harold ... 949,473
Pin. See Dowel pin.
Pipe cleaner, G. N. Cragin ... 949,622
Pipe coupling, F. C. Pahlow ... 949,329
Pipe coupling, train, H. W. Thomas ... 949,040
Pipe hanger, R. C. Hunter ... 949,576
Pipe threading tools, work holder for, B. Borden ... 949,031
Pipe wrench, J. F. Wright ... 949,107
Pipe wrench, E. A. Whetsel ... 949,307
Piston ring, W. A. Reinhardt ... 949,660
Plane guide, W. T. Whiteway ... 949,691
Plant stand, adjustable, J. M. Hamm ... 949,535
Planter seeding attachment, J. L. Baldwin ... 949,254
Plastic material mold, G. A. Harter ... 949,571
Plate or dish, child's, J. C. Matthews ... 949,023
Plow, J. H. Nicholes ... 949,493
Plow, J. G. Redmond ... 949,686
Plow, J. E. Rossetter ... 949,098
Plow harrow attachment, A. L. Lore ... 949,030
Plowshare, G. J. Buckley ... 949,617
Pneumatic cleaner, A. C. Buell ... 949,370
Pocket guard, A. J. Bulish ... 949,673
Polish device, R. M. Schaumann ... 949,045
Powder and other substances, instrument for administering, L. J. F. Nicolai ... 949,302
Power transmission device, G. A. Cutter ... 949,266
Pressure gage, differential, B. J. P. Roberts ... 949,595
Primary battery, W. C. Banks ... 949,264
Printing machine sheet feeding device, G. Kidd, reissue ... 13,063

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES

WE ARE WELL EQUIPPED to manuf. some patented article, electrical and woodworking, on royalty or other satisfactory basis. Will entertain exploiting. Electrical, Box 773, N. Y.

Inquiry No. 9018.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

## PATENTS FOR SALE

Inquiry No. 9007.—Wanted, the manufacturers of the Van Winkle Woods & Sons, and the Weber power meters.

FOR SALE.—U. S. patent rights to highest bonafide bidder April 2, 1910, telephone muffler. Telephone booths no longer necessary. See descriptive notice elsewhere in this issue. W. H. Plumb, 252 Lexington Ave., N. Y.

Inquiry No. 9014.—For manufacturers of machinery supplies etc. to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

## FOR SALE

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads 3 to 40 in. Price only $42.50. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9016.—Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

## PARTNERS WANTED

MINING PARTNERS WANTED. I want to form a mining and prospecting company for mining gravel deposit and quartz in Plumas Co. I can give the best of references. For further information address Robert Belden Paige, Butte Co., Cal.

Inquiry No. 9023.—Wanted, to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9029.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9036.—Wanted, the address of the manufacturers of "Cycle Ball Bearing Suspenders."

Inquiry No. 9038.—Wanted the address of the Chipman Electric Purifying Co.

Inquiry No. 9042.—Wanted the address of Farney Safety Razor Co.

Inquiry No. 9052.—Wanted, address of firms who install plants to manufacture nitrogen.

Inquiry No. 9055.—Wanted address of parties interested in Log Cleaning Machines.

Inquiry No. 9057.—For manufacturers of glass and china balls, used as fixtures or ornaments on lightning rod equipment, also weather vanes for same purpose.

Inquiry No. 9060.—Wanted to buy machinery to manufacture seed corn racks.

Inquiry No. 9066.—Wanted complete outfit for export for making rice-flakes and wheat-flakes.

Inquiry No. 9068.—Wanted to buy machinery for manufacturing chewing gum such as rolling, cutting or wrapping machinery.

Inquiry No. 9069.—For the address of firms making chain cloth, something like ladies' purses are made of.

Inquiry No. 9070.—Wanted, manufacturers of metal castings for art lamp shades.

Inquiry No. 9071.—Wanted, the address of parties making moulds for large concrete vases for flower pots.

Inquiry No. 9072.—Wanted, machinery for making fine chains, such as used by jewelers, etc.

Inquiry No. 9073.—Wanted, machinery to manufacture cocoanut oil; also the crude material.

Inquiry No. 9074.—Wanted to buy old model locomotives or steamboats, such as were exhibited with nickel-in-the-slot attachments in ferry houses, etc.

Inquiry No. 9075.—Wanted to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

Inquiry No. 9076.—Wanted the address of parties in Canada who could make a safety razor.

Inquiry No. 9077.—Wanted, the address of manufacturers that make small articles of wood, such as checker boards, etc.

Inquiry No. 9078.—Wanted, the address of manufacturers of sewer pipe made of fiber and asphaltum, suitable for laboratory use.

Inquiry No. 9079.—Wanted, parties to make a special steel plate rolled for "angle bars," in large quantities.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste-making machinery.

Inquiry No. 9081.—Wanted, manufacturers of a mixing machine to mix powdered and fluid ingredients to a thin dough; also molds to put such dough in to dry; the size to be about 3½ inches long, 2¼ inches wide and 1¼ inches high, making the form of a cake like sapolio.

Inquiry No. 9082.—Wanted the address of manufacturers of the bead fringe used on art shades for electric lamps, etc.

Inquiry No. 9083.—Wanted, the address of firms manufacturing small beer brewing plants, from 25 to 100 gallons a day.

Inquiry No. 9084.—Wanted, the address of manufacturers of Irwin portable bath tubs.

Inquiry No. 9085.—Wanted to buy longitudinal hollow perforated tubing.

Inquiry No. 9086.—Wanted, to buy a pine wood peeler.

Inquiry No. 9087.—Wanted a machine for hardening hack saw blades; also a machine for setting same when they have been toothed.

Inquiry No. 9088.—Wanted, the address of manufacturers of family sized peanut pulverizers for making peanut butter.

Inquiry No. 9089.—Wanted, the address of manufacturers of galvanized steel perforated hollow tubing.

Wringer roll, E. Bruegel ..... 949,564

A printed copy of the specification and drawing of any patent in the foregoing list, or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway, New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

NEW YORK, SATURDAY, MARCH 5th, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## A TRIBUTE TO AMERICAN SHIPBUILDING

ALTHOUGH the general public has apparently failed to appreciate the significance of the recent winning of a $22,000,000 order for battleships by an American shipbuilding firm in competition with the leading yards of Great Britain, France, Germany, and Italy, the importance of this matter is fully appreciated abroad.

The facts are as follows: About one year ago the Argentine government asked for proposals for two first-class battleships, and it requested four American firms and all the leading foreign shipbuilders to put in bids on the contract. The plans submitted were not accepted. The Argentine Commission then prepared its own specifications and asked bids from a selected number of these contractors. On the receipt of the second lot of bids it again narrowed the competition down to one American firm, the Fore River Company, two English firms, Vickers Sons & Maxim and the Armstrongs, and one company each from Germany, France, and Italy. As a result of this last competition the award was given to the Fore River Company on designs and price submitted by President Francis T. Bowles, formerly Chief Naval Constructor of the United States navy. One of these ships will be built at the Fore River yard and the other by the New York Shipbuilding Company.

Judging from such particulars regarding the design of the vessels as are available, they will be the most powerful fighting ships afloat at the time of their launch. Although in displacement they will not exceed our two latest battleships the "Wyoming" and "Arkansas," the disposition of their twelve 12-inch guns is such that they will have a considerably more powerful concentration of fire on every point of bearing except abeam. This advantage is secured by placing the two amidship turrets *en échelon*, or diagonally, an arrangement which permits the four guns in these turrets to be trained dead ahead or dead astern as may be desired. Since the four 12-inch guns in the pair of turrets in the bow and at the stern can be trained axially, this ship will be capable not only of concentrating all twelve guns on either broadside, as will be done by our new "Wyoming" class, but also eight guns dead ahead and eight dead astern as against a fire of four ahead and four astern for the "Wyoming." The belt is to be 10 inches in thickness and the speed 22 knots. Apparently, unless some other features of the ship have been sacrificed, this vessel represents the highest development of offensive power yet attempted in the history of warship construction.

That the American tender was lower than that of such firms as Vickers and Armstrong is explained by the fact that armor plate and the steel for the hull construction can be obtained at a lower price in the United States than it can abroad, the difference in this regard being so great as to more than offset the high cost of American labor. Whatever be the reason for our success, the fact remains that the placing of this large contract with an American firm adds greatly to the prestige of our yards, and testifies to the high point of excellence to which warship construction has been carried in this country. In this connection we may as well draw attention to the fact that the apathy of the United States to any proposed measures for the resuscitation of our merchant marine has reduced the construction of merchant vessels to such a low point that our leading shipbuilding yards are to-day kept alive almost entirely by government orders for work. Nor must it be argued that the securing of this large warship contract proves that there is no necessity for government assistance in the upbuilding of our merchant marine, for the question of the subsequent cost of running a merchant ship, which is much higher in the American than in foreign service, does not enter into the consideration of warship construction. Moreover, the competition in the construction of merchant steamers is much keener and the prices are relatively lower than for the construction of warships.

## COULD THE EARTH COLLIDE WITH A COMET?

ON May 18th next the earth will be plunged into the tail of Halley's comet and the head of that body will be but 15,000,000 miles away. It is but natural that a thinking man should ask: Is there a possibility that the earth may encounter a comet and thus come to a frightful end?

Curiously enough, it was Halley himself who first pointed out the possibility. Whiston, Newton's successor in the Lucasian chair of mathematics at Cambridge, was so alarmed at "a chariot of fire" which flared up in his day, that Halley was prompted to look closely into its movements. His work led to the startling result that the comet, when passing through the descending node, had approached the earth's path within a semi-diameter of the earth. Naturally, Halley wondered what would have happened had the earth and the comet been actually so close together in their respective orbits. Assuming the comet's mass to have been comparable with that of the earth (an assumption which we now know to have been utterly beyond reason) he concluded that their mutual gravitation would have caused a change in the position of the earth in its orbit, and consequently in the length of a year. This train of thought led him to consider what the result of an actual collision would have been, and he concludes that "if so large a body with so rapid a motion were to strike the earth—a thing by no means impossible—the shock might reduce this beautiful world to its original chaos."

Hence Halley not only dispelled the superstition and the terror which once followed in a comet's wake, but also pointed out a possibility which the superstitious Dark Ages had ever dreamed of. It seemed to Halley not improbable that the earth had at some remote period been struck by a comet which, coming upon it obliquely, had changed the position of the axis of rotation, the north pole having originally, he thought, been at a point not far from Hudson's Bay. The more recent investigations of Kelvin and Sir George Darwin completely upset any such theory.

Since Halley's time the chance of a collision between the earth and a comet has engaged the attention of many astronomical mathematicians. Laplace, for example, painted the possibility of a collision with the earth so vividly that he startled his day and generation. He drew a picture of a comet whose mass was such that a tidal wave some 13,000 or 14,000 feet high inundated the world, with the result that only the higher peaks of the Himalayas and the Alps protruded. Lalande created a panic by a similar consideration of the subject in a paper which was intended for presentation before the Academy of Sciences, but which was not read. Such was the popular excitement, that he felt himself constrained to allay the public fears as well as he could in a soothing article published in the Gazette de France. The masses assumed by both Laplace and Lalande are so preposterous that their theories are no longer seriously considered by any sane astronomer.

Since the day of Laplace and Lalande there have been several comet "scares." Biela's comet crossed the earth's orbit on October 29th, 1832. When that fact was announced, Europe was in a ferment. The orbit of the earth was confused with the earth itself. Such was the popular excitement, that Arago took it upon himself to compute the possibilities of a collision. He pointed out that the earth did not reach the exact spot where the comet had intersected the earth's orbit until a month later, on November 30th, on which date the comet was 50,000,000 miles away. Incidentally he pointed out that a collision was always happily remote. He thought that the chances of a meeting were about one in 281,000,000. Babinet, on the other hand, thought that a collision was likely to take place once in about 15,000,000 years. More recently the entire problem has been considered by Prof. W. H. Pickering of Harvard. By a collision he understands, first, that any part of the earth strikes any part of the comet's head, second, that any part of the earth strikes the most condensed point in the head (the core) as distinguished from the larger nucleus. What the average size of a visible comet's head may be, we have no means of knowing. Young estimates that for a telescopic comet it averages from 40,000 to 100,000 miles in diameter. The head of the great comet of 1811 was 1,200,000 miles, that of Holme's comet in 1892, 700,000 miles, and that of naked-eye comets generally over 100,000 miles.

In the last half of the last century 121 comets including returns penetrated the sphere of the earth's orbit. From this Prof. Pickering infers that we should expect to be struck by the core of a visible comet once in about 40,000,000 years, and by some portion of the head once in 4,000,000 years. Since comets' orbits are more thickly distributed near the ecliptic than in other regions of the sphere, the collisions would occur rather more frequently than this, but hardly as often as once in 2,000,000 years, and since it has been estimated that animal life has existed upon the earth for about 100,000,000 years, a considerable number of collisions, perhaps as many as fifty, must have taken place during that interval, in Prof. Pickering's opinion, evidently without producing any very serious results.

The old notions of the tidal effects of comets were based upon an erroneous conception of cometary masses. It seems astonishing that a man of Laplace's wonderful mathematical powers should not have concluded that a body like a comet, which can sweep through the entire solar system without deranging a single one of its members, must have a mass so small that it cannot appreciably affect the waters of the earth. As it is, comets are more likely to be captured by planets (witness the comet families of Jupiter and Saturn) than to derange a member of the solar system or to produce tidal effects.

The plunging of the earth in the tail of Halley's comet naturally causes many to wonder what will be the effect upon the inhabitants of the earth. Similar passages occurred in 1819 and 1861, but no one was the wiser until long after. Some astronomers claimed to have noticed auroral glares and meteoric displays at the time, but whether these were really associated with the comet or not cannot definitely be stated. At all events, it may be safely held that on May 18th next none of us will be aware of the fact that we are literally breathing the tail of Halley's comet. From this it may well be inferred that the wild tales of the possible effects of poisonous gases, tales for which the newspapers are very largely responsible, are utterly without foundation. It is true that a comet's tail is composed of poisonous and asphyxiating hydrocarbon vapors and of cyanogen, but it is also true that the actual amount of toxic vapor is so small that when the earth is brushed by the tail of Halley's comet, the composition of the atmosphere will not be so affected that a chemist could detect it. Flammarion has drawn a vivid picture in his "La Fin du Monde" of the possible effect of passing through a tail highly charged with vapors. He has shown us terrified humanity gasping for breath in its death struggle with carbon monoxide gas, killed off with merciful swiftness by cyanogen and dancing joyously to an anæsthetic death, produced by the conversion of the atmosphere into nitrous oxide or dentist's "laughing gas." No one of any common sense should be alarmed by these nightmares, particularly when it is considered that so diaphanously thin is a comet's tail, that stars can be seen through it without diminution in brightness.

## PATENT COMPLEXITIES IN GREAT BRITAIN.

IN the course of a judgment in an important patent case before the House of Lords, the supreme tribunal of Great Britain, the Lord Chancellor made very pointed references to the complexity with which patent specifications are sometimes encumbered. During the past few years there has been an increasing tendency to render such specifications as intricate and as voluminous as possible, thereby obscuring the vital issue. Only a few weeks previously the Chancellor complained in another action of the manner in which claim and narrative had been so intimately interwoven that considerable difficulty was experienced in unraveling the real factors in the issue. Such a tendency, the Lord Chancellor pointed out, defeated its own object, for where patent specifications and claims were so framed as to puzzle a student, business men were afraid to take out a license for its working, for fear their interpretation of the patent might be found to be erroneous, be found guilty of infringement, and be mulcted in heavy damages. The particular case in which the Lord Chancellor was constrained to make these comments was in connection with improvements in the casting and trimming of stereotype plates. The court contended that the specification of the original patent was extremely voluminous and complicated, amounting almost to the bulk of a treatise, in which there was infinite redundancy and repetitions, and constant references to illustrations which were somewhat difficult to follow. It was a document which needed a prolonged and penetrating study in order that any one who wished to work out problems in this particular field of industry might know how to avoid all possible risk of infringement.

In the course of his remarks the Lord Chancellor pointed out that inventors who drew up such complicated claims must run the risk of the whole patent's being declared void by the court on the plea of ambiguity. The framing of specifications in this manner he declared to be an abuse of the law, and he gave the warning that it would be checked, if the occasion arose, by the simple process of declaring the patent invalid. These timely remarks have been greatly appreciated by British commercial and manufacturing establishments, and there is no doubt that advantage will be taken to draw up specifications in a more concise and lucid manner.

## ENGINEERING.

**The Chanute medal**, founded by that celebrated engineer, Octave Chanute, and awarded by the Western Society of Engineers for the best paper presented during the year, has been given to Prof Talbot, University of Illinois, for his paper entitled "Tests of Cast Iron and Reinforced Concrete Culvert Pipe," which embodied results of a research extending over a number of years.

**The Interstate** Commerce Commission points with pardonable pride to the saving of life and limb which has resulted from the operation of the safety appliance law In 1893 one out of every 349 men employed in car coupling was killed, and one in 13 was injured, whereas in 1908, one out of 983 was killed, and one out of 62 was injured—an increase in the factor of safety against death of 181 6, and against injury of 377

**In addition** to the three dreadnought battleships which are being built for the Brazilian navy, the programme of construction includes ten destroyers of the staunch seagoing type being built by Messrs Yarrow Six are in commission and the seventh recently exceeded her speed of 27 knots during trials on the Clyde, carrying a load of 100 tons. These vessels are 240 feet long and they are propelled by twin reciprocating engines of 8,000 horse-power

**Elon J. Arnold** has been appointed subway engineer for the city of Chicago, and it is probable that about nine miles of subway will be put under construction forthwith. The city has sufficient funds for this purpose from its accumulation from the street railway company's dividends, and the street-car companies are bound to contribute $5,000,000 The first section will be built in the heart of the city, and will form the center from which later construction will radiate

**There is** much significance in the recent capture by the Germans of several big contracts in this country The Rhenish-Westphalian works have contracted to build three more 10,000-horse power turbines for the Niagara Falls power plants, which will make fifteen in all with a total horse-power of 150,000 Other German firms have obtained orders to build a series of large coke ovens for the Bethlehem Steel Company The order includes 400 ovens with a capacity of 3,000 tons a day, and the cost will be about $4,500,000

**There is** much talk in the air about the construction of a 30,000-ton battleship for the United States navy and its cause is to be found in the advent of the new and very powerful 14-inch gun, which recently underwent successful tests at Sandy Hook. If the 14 inch gun is to be installed, and the total number of guns is to remain the same as in the "Wyoming," an increase in displacement becomes necessary Indeed, it is questionable whether even a 30,000-ton ship could mount twelve 14-inch guns and give them adequate protection.

**Only those** who have witnessed the great congestion on the present subway can understand the supreme satisfaction afforded by the determination of New York city's very efficient Mayor and the Public Service Commission to build at once an additional system of subways at a cost of $100,000,000 The routes include an entirely new north and south subway from the Bronx to the Battery by way of Lexington Avenue and Broadway, and a subway in Brooklyn connecting the lines over the Williamsburg Bridge with the new Fourth Avenue route in Brooklyn, the latter to have elevated extensions to Fort Hamilton and Coney Island

**The Federal authorities** have approved of plans for the opening of the Delaware River to a navigable depth of 12 feet as far as the city of Trenton, and it is believed that the development of deep-water navigation farther inland will be only a question of time. In Europe stupendous work of this character has been done Manchester spent $80,035,000 on the 35-mile canal, which has made the city of Manchester a seaport, while Duisberg in Germany, 100 miles from the mouth of the Rhine, and Cologne, 150 miles from the sea, are both in free communication by water with the seaboard.

**Mr. George Gibbs**, Chief Engineer of Electric Traction of the Pennsylvania Tunnel and Terminal Railroad, in a report made at the last session of the International Railway Congress gives some comparative figures of economy of the West Jersey and Seashore Railway and the Long Island Railroad on lines that were formerly operated by steam. During 1908 the Long Island Railroad operated its electric line at 17.80 cents per car mile as against a cost of 27.95 cents for steam train mileage. On the West Jersey and Seashore the costs were 20.46 cents for electric as against 22.30 cents for steam mileage. The relatively unfavorable results on the latter railway are accounted for mainly by the fact that stops were frequent on the steam service of the Long Island Railroad and the steam service therefore was costly; whereas on the West Jersey Road the average number of cars per steam train was twice that of the electric, and much of the service was express with few stops and therefore of an exceptionally economical character.

## ELECTRICITY.

**The first Edison medal** of the American Institute of Electrical Engineers was awarded to Prof Elihu Thomson for his achievements in electricity, on the occasion of the anniversary dinner of the Institute This medal was founded by friends of Mr Edison, and is intended to commemorate his work

**A remarkably long wireless transmission** was recently recorded by the steamship "Tennessee," five days out from Honolulu, which succeeded in catching a message from Table Bluff on the coast of California. The message was a weather report, which was afterward verified by the Navy Department The distance of transmission was 4,580 miles

**A recent test of wireless telephony** was made to show its value for transmitting music Several selections were sung in a transmitter at Park Avenue and Fortieth Street, New York, and were listened to by a group of newspaper men at the Metropolitan Tower At times the singing was very clear, but frequently it was impossible to hear anything but a confused blur of sound

**A portable transformer drying apparatus** has been devised to dry out transformers that have become moist during shipment or storage The apparatus consists of a furnace adapted to burn wood or charcoal A current of air heated by the furnace is forced through the transformer by means of a blower driven by a small motor The air, before reaching the blower, is filtered through several thicknesses of cheesecloth

**The telephones** used on the steamship "Lusitania" are quite interesting The induction coil condenser, and bell of the instrument are inclosed in a small white enamel box, and the switch hook which projects from one side is provided with a special retaining device to prevent the receiver from being knocked off by the motion of the ship The receiver is allowed to rock on the hook, otherwise the lever would lift and make a false connection when the ship was pitching and rolling

**A recent number** of the Electrical World describes a very interesting electrical installation on an Illinois farm The power plant consists of a gas-producer installation supplying a 25-horse-power two-cylinder gas engine to which a 16-kilowatt 125-volt direct-current generator is belted The engine also runs a pump which supplies an elevated water tank The current is used to light 150 lamps, which are used in the family residence and a tenant house, as well as in various barns, corn cribs, and other buildings

**A new type** of long-distance telephone was recently tested successfully over a circuit extending from New York to Chicago by way of Pittsburg, and return The distance was 1,825 miles The system, which is the invention of Dr Tardieu of Arles France consists in raising the pitch of the message two octaves and a third by means of a combination of drums At this high pitch the waves are sharp and short, and can be transmitted over a greater distance than is possible with the sound waves of ordinary conversation At the receiver the pitch is again restored to normal

**At a recent meeting** of the Institute of Electrical Engineers in London a differential electric thermometer was described by Prof J A. Fleming The thermometer consists of two large glass tubes, sealed air tight at the top and bottom and connected by a tube of fine bore in which is a thread of colored water containing a bubble of air in the center The strips whose resistance is to be measured are placed in the tubes, and one of them is connected with a source of high frequency current while the other is connected with a source of direct current By introducing resistance into the circuits, the heat may be regulated until it is the same in both tubes, as will be indicated by the bubble remaining in the center of the small connecting tube The value of the resistances will vary inversely as the square of the current

**A report** on the trackless trolley systems near Vienna has recently been made by the United States Consul General there situated The current collector used consists of a small frame supported on the grooved wheels which run on the positive and negative wires. The wheel is prevented from jumping the wires by a weighted pendulum A cable of about 10 or 12 yards connects the current collector with the car When two cars meet, the trolley connections are interchanged, and they can proceed on their way This is an improvement over the track system with turn-outs at various points, which make it necessary for the first car that reaches the turn-out to wait until the second car arrives. The total running cost of this system for a car operating 75 miles a day is from $5 20 to $6 80 or from 7 to 9 cents per mile

**A five-mile test** of the Edison Beach storage battery car was made here last week over the 29th Street horse-car tracks. The car carried a number of engineers, who were to judge of its availability for street-car service in New York. If their decision is favorable fifteen of the cars will be put into service.

## SCIENCE.

**Dr. E. E. Barnard** of Yerkes Observatory secured photographs of Comet A 1910 on January 21st, 24th, and February 1st, 3rd, 4th, and 6th Cloudy weather prevented the taking of any other photographs Dr Barnard informs us that one of the interesting features of this comet was an extension from the head about one-quarter of a degree long toward the sun This extension was in a line with the prolongation of the southern edge of the tail

**The mechanical** laboratory of the Polytechnic Institute of Worcester, Mass, has undertaken a study of the relative thermal conductivity of rolled copper and of copper deposited by electrolysis and not rolled The conductivity of the rolled copper was found to exceed that of the electrolytic copper by 30 per cent. This is an interesting instance of the change in the internal structure of metals which is produced by mechanical treatment

**Cobalt and tin**, in the liquid state, are miscible in all proportions, but solid cobalt dissolves only about 3½ per cent of tin The two metals form two definite compounds CoSn and $Co_2Sn$ Cobalt and antimony also mix in all proportions in the liquid state Solid cobalt can take up 12½ per cent of antimony, with which it forms the compounds CoSb and $CoSb_2$. Cobalt and lead form no definite solid compound and, even in the liquid state each dissolves only a small quantity of the other The same law governs the alloys of cobalt with bismuth and thallium. Cobalt and zinc, fused together, deposit alloys in which the definite compound $CoZn_4$ has been found Cobalt and chromium mix in all proportions in the solid as well as in the liquid Cobalt and silicon mix in all proportions, in the liquid state, and form five definite solid compounds $Co_2Si$, CoSi, $CoSi_2$, CoSi, $Co_3Si$ These recent determinations possess especial interest as very little study has been given to the alloys of cobalt

**European sportsmen** are beginning to fear that game will be made scarce by the multiplication of aeroplanes, balloons, and other aerial vessels It is well known that where many kites are habitually flown they have the effect of driving the game to other districts The effect of a kite however, is very small in comparison with that of an aeroplane or a dirigible balloon A German landowner, strolling over his estate saw two black storks which had been standing, with a number of ducks, on the bank of a pond, suddenly take to flight, without apparent reason The next instant the ducks quacking loudly, took wing and were soon out of sight Looking around for the cause of the birds' affright the proprietor saw a dirigible balloon, which the birds had probably perceived before it became visible to him He learned afterward that deer browsing in the fields, had been frightened by the sight of the airship or by the noise made by its propellers and had fled to the forest All animals are terrified by airships Partridges quail, and other game birds crouch and hide while domestic fowls utter loud warning notes the instant they perceive the monstrous bird of prey The Swedish aeronaut Von Hoffken, while sailing at a moderate elevation observed that elks, foxes hares and other wild animals fled at his approach and that the dogs ran howling into the houses While the Zeppelin III was going from Düsseldorf to Essen the aeronauts on board noted that horses and cattle galloped frantically over the fields on catching sight of the airship

**One of the** scientific developments of recent years has been the formation of international organizations for the consideration of important subjects International congresses in zoology in chemistry in medicine and in other subjects meet at regular intervals usually every three years, for the purpose of freely discussing the problems of their specialties These have resulted in international committees Thus it happens that there is an International Union for Solar Research, with a special committee on solar radiation The desirability of establishing an international scale for the comparison of observations in solar radiation is obvious It is fortunate that Mr C G Abbot, director of the Smithsonian Astrophysical Observatory has succeeded in perfecting the construction of an instrument used for such a purpose which is called "pyrheliometer" These instruments, tested by him both in Washington and at Mount Wilson in California have been found to yield satisfactory results A limited grant from the Hodgkins fund of the Smithsonian Institution was made for the construction of four of these silver disk pyrheliometers These have now been completed and are about to be sent to investigators in widely separated localities for use in obtaining constants The first of these instruments will be sent to M Violle who is chairman of the committee on solar radiation of the Solar Union, and by him will be placed in the meteorological station established by the French government on the Pic du Midi in the Pyrenees in the south of France The second will go to M Chistoni of the Physical Institution in Naples and will be sent to the observatory on Mount Vesuvius.

# TWO REMARKABLE SHOWS

## NOVELTIES IN MOTOR BOATS AND AEROPLANES

The sixth annual motor boat show to be held in Madison Square Garden opened on February 19th and lasted one week. The show this year was larger than ever before, there being a great number of boats of various speeds and sizes exhibited. These varied from 10 feet to 40 in length, and in motive power from 1 to 100 horse-power. Altogether some fifty boats of various types were exhibited, representing a total value of $[illegible]. The largest exhibit of any one firm was that of the Electric Launch Company of Bayonne, N. J. In addition to an electric launch having a radius of 100 miles on one charge, this company showed a 21-foot mahogany yacht tender fitted with a 40-horse-power gasoline motor and capable of a speed of 22 miles an hour, a larger boat fitted with the same size motor and having a speed of 18 miles an hour, and a 35-foot craft fitted with a 6-cylinder 60-horse-power motor and capable of a speed of 23 miles per hour with six or eight passengers. The most pretentious "Elco" was a high-speed 54-foot cabin launch fitted with a 60-horse-power 4-cylinder Standard motor, and capable of a speed of 15 miles per hour. This boat has a large open cockpit fore and aft for fair weather, and a spacious cabin amidships. The engine is placed forward in a separate compartment and the controlling levers and steering wheel are placed side by side. Other firms exhibited cruisers comparable in size to the boat just mentioned and fitted with all the conveniences needed on this type of craft.

# RAPID PROGRESS OF THE NEW YORK STATE BARGE CANAL

## A RECORD OF RECENT ACHIEVEMENT

The large amount of work done on the New York State Barge Canal during the past year augurs well, not only for the completion of this great work within the contract time but for its being done within the estimate of total cost of $101,000,000. Almost as much construction work was completed during the aggregate of the work under contract is $54,138,329. It is satisfactory to know that this has been accomplished at a saving of $2,653,208 over the estimate of 1903 for the same work. Construction work to the value of more than $16,000,000 has been done, nearly one-half of it during the year 1909, fifteen out of the ing Lake Erie at Buffalo at an elevation of 565.6 feet above sea level the new canal follows the Niagara River to Tonawanda Creek and thence runs easterly to the Oswego River and to a junction with the Hudson River at Waterford. After entering Tonawanda Creek it follows the stream to Lockport, where a de-

RAPID PROGRESS OF THE NEW YORK STATE BARGE CANAL

year as was accomplished during the whole period of construction preceding, and the plans that were worked out to completion equal 80 per cent of the amount of similar work done in any previous two years, that is, if we consider the mileage and the size of the estimate.

On January 1st, 1910, some 314 miles of the canal, or 75 per cent of the entire work, were under contract, the remainder of the plans were nearing completion and will soon be ready for letting, and the fifty four locks are practically completed, and by the spring of next year the eight movable dams of the Mohawk River will be in operation. The work has now reached a stage where it is possible to predict both the time and cost of the completion of the entire project.

By studying the accompanying map, profile, and cross sections of the canal in connection with the following outline of its principal features, an adequate conception of this great work may be gathered. Leav-

scent of 101 feet is made by means of two locks; thence there is a 60-mile level to Rochester. Beyond Rochester the new canal coincides with the old canal until it enters the River Clyde near Lyons. Beyond Lyons the old canal route is abandoned and a new route is laid to the north of the old work. The Clyde River and the Seneca River are followed to Three Rivers, where the Seneca and Oneida unite to form the Oswego River. A new stretch of canal will be formed in the bed of the river, running north to Lake Ontario, the

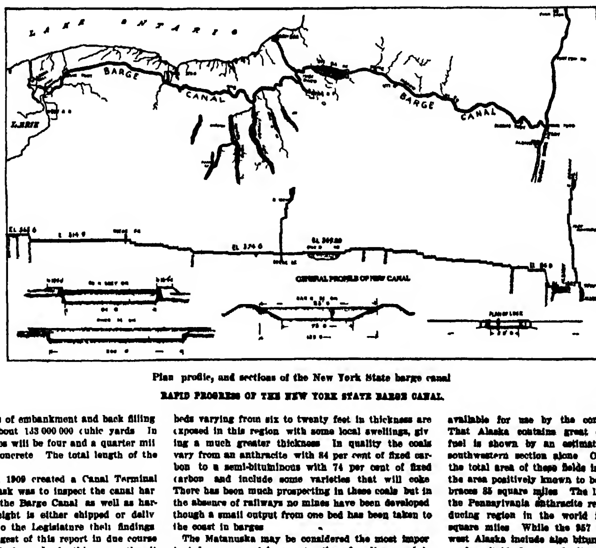
depth of the river being increased by the use of fixed dams From Oswego River the canal extends easterly following the river to and across Oneida lake and through the valley of Wood Creek to the city of Rome Here the canal crosses the divide by a series of locks and enters the valley of the Mohawk River

The canal in the valley of the Mohawk between Utica and Schenectady will be provided with nine movable and two fixed dams eight of the movable dams will have a maximum lift of 15 fe t and a maxi mum depth on the sills of 20 feet and these struc tures will s rve to control the high floods of the Mohawk Th canal enters the Hudson River at Water ford by a series of five locks whi h will bring it down from an elevation of plus 1 1 feet to tide level From Waterford the important branch known as the Cham plain Canal runs north to the lake As far as Fort Edward the location lies in the Hudson River and beyond Fort Edward it will be on an entirely new location making entry into Lake Champlain through Wood Creek whi h will be canalized by the use of fixed dams The Canadian government has planned the construction of a waterway with a depth of 12 feet from th mouth of th new canal through Lake Champlain to Montreal

Naturally a work of this magnitude passing through an undulating country and through several important cities involves an immense amount of structural work in the way of dams locks bridges and other masonry and steel work There will be a total number of fifty four locks whose lift will vary from 6 feet to a maxi mum of 40½ feet these taking the place of the seventy two locks of the old canal All of the locks will be 45 feet wide with a workable length of from 300 to 310 feet The masonry work throughout the whole canal will be of con crete All lock gates will be of steel electrically operated For the control of rivers and streams and the impounding of water for sum mit supply there will be thirty five dams of the fixed and movable types

The total quan tities of excava tion and construc tion are necessar ily very large in cluding in round numbers 58 000 000 cubic yards of dredging 56 000 000 cubic yards of earth excavation, 11 000 000 cubic yards of rock ex cavation and about 10 000 000 yards of embankment and back filling making a total of about 135 000 000 cubic yards In the masonry structures will be four and a quarter mil lion cubic yards of concrete The total length of the canal is 442 miles

The Legislature in 1909 created a Canal Terminal Commission whose task was to inspect the canal har bors connected with the Barge Canal as well as har bors where canal freight is either shipped or deliv ered and to report to the Legislature their findings We hope to give a digest of this report in due course in the columns of this journal In this connection it is of interest to note that the interest of the Federal government has been enlisted in the project to form a large terminal harbor in Jamaica Bay with entrance channels at sufficient depth to accommodate seagoing vessels This improvement will have an important bearing on the question of canal terminal facilities



Plan profile, and sections of the New York State barge canal

RAPID PROGRESS OF THE NEW YORK STATE BARGE CANAL.

## The Anthracite Coal Beds of Alaska.

BY DAY A[illegible] WILLEY

The extent of its gold and copper deposits has given Alaska its principal reputation for mineral resources The quality and area of these ores have called public attention to th m to the neglect of other minerals and the bulk of the mining in the territory has been done to secure these ores Consequently coal mining and lumbering are practi ally undeveloped industries

Although the geologist and mineralogist have been in[illegible]igating in Alaska for a period of years most of th[illegible] ork has been confined to the region along the coa[illegible]d the terr tory traversed by navigable rivers [illegible] the Yukon. Owing to the difficulty of examin ing and mapping the interior and especially the north ern portion of Alaska, accurate information of its min eralogy is available in but a small fraction of its total area Here however the study of the formation has been so thorough that the existence of very large de posits of coal has been revealed and accurate esti mates made showing the locations of the veins also the thickness while the quality of the fuel has been carefully analyzed by elaborate tests It may be added that the conclusions of the United States Geological Survey agree with the reports of experts who have been sent to Alaska to get data for mining and invest ment companies

The investigation of the coal bearing area has been largely centered in the vicinity of the coast and two regions have been so thoroughly examined as to prove that fuel is another resource of Alaska of great im portance Though Tertiary coal bearing rocks are known to cover a considerable area in the southern part of Admiralty Island and on adjacent islands of southeastern Alaska the included coal of this region has little present fuel value The beds are from a few inches to two or three feet in thickness and the coal is of a low grade lignitic character There are two known areas of high-grade coal—the Bering River field in the Controller Bay region, and the Matanuska field north of Cook Inlet. The Bering River field ly ing about 25 miles from tidewater at Controller Bay embraces 2 64 square miles containing anthracite and 20 2 square m les bituminous coal The coal bearing rocks trend to the northeast into the unsurveyed high ranges and it is quite possible that there may be an extension of the coal fields in this direction Coal beds varying from six to twenty feet in thickness are exposed in this region with some local swellings, giv ing a much greater thickness In quality the coals vary from an anthracite with 84 per cent of fixed car bon to a semi-bituminous with 74 per cent of fixed carbon and include some varieties that will coke There has been much prospecting in these coals but in the absence of railways no mines have been developed though a small output from one bed has been taken to the coast in barges

The Matanuska may be considered the most impor tant for commercial purposes thus far discovered in the territory owing to its accessibility This field lies about 25 miles from tidewater at Knik a northerly embayment of Cook Inlet. As Cook Inlet is frozen during the winter however the distance to an open seaport must be measured to Resurrection Bay on the east side of Kenai Peninsula, about 150 miles from the coal field There are several months of the year when Cook Inlet could be used as a waterway

The coal of these deposits as investigated by Alfred H Brooks the eminent mining expert associated with the Geological Survey varies in quality from a sub bituminous to a semi bituminous, with some anthracite, and is included in folded and faulted Tertiary or Eocene shales sandstones and conglomerates, aggregat ing 3 000 feet in thickness The coal beds vary from 5 to 36 feet in thickness and the total area known to be underlain by coal aggregates 46½ square miles. How ever as much of the field is covered by gravels and none of it has been surveyed in detail, the coal-bearing area may be much larger. The total area of what may prove to be coal-bearing solely is [illegible] the square miles Up to the present time there has been no means of transporting this coal to market, so that as stated no mining has been done, but many beds have been opened in prospecting

The chemical analysis of specimens of coal taken from a large number of veins practically covering this entire district gives the following results

| | Moisture | Volatile Matter | Fixed Carbon | Ash | Sulphur |
|---|---|---|---|---|---|
| Anthracite— | | | | | |
| Bering River average of seven analyses | 7 [illegible] | 8 15 | [illegible] | 7 74 | 1 [illegible] |
| Matanuska River | [illegible] | 7 08 | [illegible] | [illegible] | [illegible] |
| Bituminous— | | | | | |
| Matanuska River cok ing, average of sixteen analyses | [illegible] 71 | [illegible] | [illegible] | 11 [illegible] | [illegible] |
| Subbituminous— | | | | | |
| Matanuska River | [illegible] | [illegible] 40 | 40 44 | [illegible] | [illegible] |
| Koyukuk River one sample | 4 47 | [illegible] | [illegible] | 12 [illegible] | |
| Nation River one sample | 1 [illegible] | [illegible] | [illegible] | [illegible] | [illegible] |
| Alaska Peninsula, aver age of five analyses | [illegible] | [illegible] | 40 13 | [illegible] | [illegible] |
| Cape Lisburne, average of eleven analyses. | [illegible] | [illegible] | [illegible] | [illegible] | [illegible] |
| Anaktuvak River one sample | [illegible] | [illegible] | [illegible] | 12 [illegible] | 0.54 |

Since the anthracite coal deposits of Pennsylvania would be naturally contrasted with Alaskan as a fuel element some analyses of the more notable Pennsyl vania grades may be given

| Pa. Region | Water | Volatile Hydrocarbon | Fixed Carbon | Fuel Ratio. | Ash | Sulphur. |
|---|---|---|---|---|---|---|
| Wilkesbarre | [illegible] | 4 [illegible] | [illegible] | [illegible] | [illegible] | [illegible] |
| Lehigh | 1 [illegible] | [illegible] | [illegible] | | [illegible] | [illegible] |

A comparison of the analyses of the coal in the Matanuska field and the two regions yielding the high est grade of an thracite in Penn sylvania would indicate that the Alaskan is of slightly better quality for gener ating heat. Its percentage of fix ed carbon 84 22 is greater than the percentage in the Wilkes-Barre region while the percentage of ash is 2 66 less than the other The proportion of sul phur 0 57 is the least in any an thracite coal found thus far in America.

While the area of the Matanuska region is limited in comparison with the Appala chian field it is but a small area of the territory known by exami nation to contain deposits of an thracite and bitu minous many available for use by the construction of railways That Alaska contains great deposits of high grade fuel is shown by an estimate of the beds in the southwestern section alone On a conservative basis the total area of these fields is 957 square miles, and the area positively known to be underlain by coal em braces 85 square miles The latest estimated area of the Pennsylvania anthracite region—the greatest pro ducing region in the world for this grade—is 480 square miles While the 957 square miles of south west Alaska include also bituminous and lignite of a grade suitable for use, the lignite is contained in only about one-fifth of the area, or less than 200 square miles the remainder representing bituminous and an thracite territory; but as already stated the experts who have explored this region agree that the anthra cite deposits that can be economically mined and made easily accessible by rail to seaports form a fuel re source of such proportions that it would supply Alaska and the Pacific States for an indefinite period

The formation in the Matanuska is such that many of the veins can be reached by short tunnels without the need of vertical shafts while the expense of elevat ing may also be avoided The veins frequently out crop on the surface. In short the natural location permits mining at a minimum cost

The beds referred to are not distant from the extens ive copper mines located near the Copper River and exploited by the Guggenheim syndicate. In connec tion with this industry a railway [illegible] has been completed to the [illegible] for the purpose of [illegible] by water. [illegible]

[illegible] the company to begin the building of a railroad in this field, as a route is available over which a railway can be easily constructed owing to the formation of the country. It will be about 175 miles in length. Another route has also been surveyed over the route already referred to, terminating at Resurrection Bay. This would allow water transportation at all seasons of the year because of the freedom from ice, while the depth of the bay is such that the largest ocean carriers can take on cargoes at the coal piers. Up to the present time this great coal field has been unproductive on account of no transportation facilities, the only operations being for test purposes. This region is of unusual interest at present owing to the Congressional investigation of the timber and mineral resources of the territory in connection with the Ballinger-Pinchot controversy.

Coal was found near Cook Inlet by the Russians as far back as 1855, but the entire output of the territory has been insignificant, as shown by the product of less than 10,000 tons of all kinds in 1909—none of it anthracite.

## THE "UTAH"—OUR LATEST DREADNOUGHT

The spirited drawing on the front page of this issue represents our latest dreadnought, the "Utah," recently launched from the yards of the New York Shipbuilding Company, Camden, N. J. She is shown steaming in a gale of wind against a heavy Atlantic sea, and in spite of her great length of 521½ feet the huge vessel as she rides over the long Atlantic rollers will do her full share of pitching and rolling as she climbs and descends each majestic sea. Several cable lengths to starboard is a sister ship that is running down the slope of a sea whose crest is sufficiently high to hide all but the funnels and masts.

These conditions are no mere creations of the artist's fancy; for we have recently seen a series of pictures taken on our fleet when it was steaming northward in a heavy gale on the Pacific, in which only the tops of the funnels and the fighting masts of some of the vessels are visible, the ships lying deep in the trough of the waves.

But although the "Utah," in spite of her full load displacement of over 23,000 tons, will be to some extent the sport of the elements, her great weight and size will make her a far steadier gun platform than is afforded by the 16,000-ton "Connecticut" or the 12,000-ton "Maine," and herein lies one of the most important advantages of the big over the medium-size warship. The "Utah," which is a sister ship to the "Florida," now nearing completion at the New York navy yard, is 521½ feet long, 88 feet 2½ inches wide, and on a normal displacement of 21,825 tons her draft is 28 feet 6 inches. At normal displacement it should be explained she will have a full supply of ammunition and two-thirds of full supply of stores and fuel. The ship is an enlarged and improved "North Dakota," with 3 feet more beam, 1 foot 7 inches more draft, and 1,825 tons additional displacement. She is equipped with 4 screw Parsons turbines of 28,000 horse-power, which are designed to give her a contract speed of 20.75 knots. She will carry 2,500 tons of coal and 400 tons of oil fuel, and steam will be supplied by boilers of the Babcock & Wilcox type. The "Utah" will be manned by 60 officers and 954 men, her total complement being 1,014. This is about the number of men that were carried on the old wooden three-deckers of the largest size, and in this ship for the first time the crew of a modern battleship equals that of one of the olden days.

Like the "North Dakota" and "Delaware," the "Utah" carries ten 12-inch guns in the main battery. They are mounted in pairs in balanced turrets, the disposition of which is shown very clearly in our engraving of the ship. The foremost pair of guns has an elevation of about 30 feet above the normal waterline. The second pair has a command of about 40 feet. The guns of turret number 3 have a command of about 33 feet, and those in numbers 4 and 5 of about 25 feet. All of the guns being mounted on the center line, they can all be trained on either broadside. Dead ahead the "Utah" can fire four 12-inch guns, and the same number dead astern. It will thus be seen that maximum broadside fire is gained at the expense of end-on fire; for the "Minas Geraes," recently built for the Brazilian government, can fire eight guns ahead or astern, and the German and British battleships six guns. Most of the fighting, however, is in all probability, will be from broadside to broadside; and the center line disposition, which originated in the Bureau of Construction and Repair, is probably the most effective [illegible]

[illegible] of sixteen 50-caliber [illegible] are carried [illegible] the gun [illegible] four [illegible] of the main [illegible]

water, and of the guns is exceptionally well worked out in these vessels, being in this respect an improvement even on the "North Dakota" herself, one of the best protected ships ever built. In the first place, with a view to limiting the destructive effects of a torpedo blow, particular attention has been paid to the question of cellular and compartmental subdivision. Even in the event of most serious underwater injury, such as might be done by a floating mine, the ship is able to concentrate on any compartment or set of compartments such a great capacity of pumps that she would be able by the aid of these alone greatly to mitigate the effects of such a blow.

The armor plan of the "Utah" is probably the most complete and effective yet put upon any ship. The main belt, over 8 feet wide, has an average thickness amidship of 11 inches. Above this is a second belt 8 feet wide of an average thickness of 9 inches. The lower waterline belt is continuous from stem to stern, and the upper belt extends from the wake of the forward to the wake of the aftermost turret. The turrets of the 12-inch guns have from 12 to 8 inches of protection. The 5-inch secondary battery amidships is protected by 6½ inches of armor, and a similar thickness protects the casemates of the six guns at the bow and stern. Between each pair of 5-inch guns is a splinter bulkhead of 2-inch armor, and back of each battery is a longitudinal wall of 3-inch armor which closes in each 5-inch gun. To reach the base of the smokestacks any shell would have to pass through 9½ inches of armor—a superb protection.

It will be noted that the ship is provided with two of the new lattice-work fire-control masts with which all our latest ships have been equipped. The handling of the boats is done by two boat cranes placed abreast of each other, one on either side of the after smoke stack. In this ship, as in all our dreadnoughts, the officers are berthed on the main deck forward below the forecastle deck, the crew accommodation being aft. This places the officers near the bridge and convenient ly to their post of duty.

The keel of the "Utah" was laid March 1th 1909, so that considerably less than a year has elapsed between the laying of the keel and the launch. In less than a year from the present time, if all goes well, this fine ship will have her trials, a speed in warship construction which is greatly to the credit of the New York Shipbuilding Company. Particular interest will attach to the trials of this vessel, for the reason that she will be the first of American battleships to be propelled by 4-screw Parsons turbines.

### American Homes and Gardens for March

The current number of American Homes and Gardens contains pictures of interesting California bungalows costing from $1,000 upward, an article on the furnishing of the apartment by a well known author, an article on the interior decoration of the home devoted to appropriate wall papers for the various rooms of the house, and views of a number of interesting houses showing interiors, exteriors and floor plans. The fourth prize garden of the American Homes and Gardens competition is also published in this issue, as well as garden notes devoted to fifteen good lilies. There is also an article on open-air orchard heating, and an article on the combined forcing bed and storage pit. One of the most interesting articles of the paper, one which is profusely illustrated, describes the water gardens of California. "Trimming street and lawn trees," a timely subject, is well treated by an experienced writer. The historic mansions of the Rappahannock River are always interesting, and the illustrations of "Kenmore," the home of Betty Washington, is one of the important features of this number.

### The Current Supplement

The current SUPPLEMENT, No. 1783, contains an unusual number of timely and interesting articles. Dr. M. Wilhelm Meyer asks, "What would we do if one of these days the sun were extinguished?" He considers the problem most instructively. Prof. O. N. Witt, the distinguished German chemist, contributes an article on the development of technological chemistry during the last forty years. An abstract is published from a paper read before the Society of Civil Engineers by M. Georges Claude on some interesting industrial applications of liquid air and oxygen. A most interesting equatorial telescope is in operation at the Urania-Zürich Observatory in Switzerland. This instrument is described by Mr. F. C. Perkins. Some photographs are reproduced which were taken by a photographer whom Latham recently took aloft with him at Louvercy, France. The pictures are probably the first ever published in this country taken from an aeroplane. Mr. Marconi's Nobel prize lecture on progress in wireless telegraphy is concluded. Lieut. John C. Soley, U. S. N., writes on the seismic period of 1909. As the result of investigations carried on during the last seventy-five years it has become possible to establish on a firm basis criteria for instituting exact comparisons of the structure of the brain in the various groups of vertebrates. These criteria are discussed in an article entitled "The Evolution of the Brain."

## Correspondence.

### HOW TO MAKE THE "ALABAMA" AND "MAINE" INTO PRE-DREADNOUGHTS

To the Editor of the SCIENTIFIC AMERICAN:

As a reader of the SCIENTIFIC AMERICAN I am particularly interested in the articles on the naval development.

I wish to know through your paper why the following changes would not be practical in remodeling the battleships "Idaho" and "Mississippi." Bearing in mind the results gained by adding 20 feet in length to the "Maine" class over the "Oklahoma," which equals 948 tons displacement, 5,603 horse-power, 2 knots speed, 2 6-inch guns with ammunition and 400 tons of coal.

I would cut these ships in two just aft the boiler rooms and build 30 feet, keeping as near the same beam as possible, 77 feet. This 30 feet would be used almost entirely for boilers, engines and coal.

I think that another set of boilers could be installed, adding one-half to the boiler power. A new set of engines would have to be built to handle the 15,000-horse-power thus developed, and I think that the speed would be raised at least 1½ knots, not much of an increase, but enough to allow these ships to steam with the 18-knot "Louisiana" class without reducing the speed of the whole fleet to 17 knots. I would replace the 8-inch guns with four 10-inch 4-caliber guns and add two 7-inch and four 3-inch guns to their present batteries. Thus we would have the following results:

| Present | Remodeled |
|---|---|
| Length, 375 feet, to | 405 feet |
| Beam, 77 feet, to about | 78½ feet |
| Displacement, 11,000 tons, to about | 14,500 tons |
| Horse-power, 10,000, to about | 15,000 H. P. |
| Speed, 17 knots, to about | 18½ knots |
| Bunker capacity, 1,700 tons, to about | 2,100 tons |

Battery, 4 12-inch, 4 10-inch, 10 7-inch and 16 3-inch guns. The armor to remain the same as originally designed.

This would be a rather costly change, but when a warship is needed the expense is a small item, and these two ships, with the increased speed and heavy batteries, would be a welcome addition to our first line of pre-dreadnoughts.

W. W. BASS.

Chicago, Ill.

[Such changes as are suggested by our correspondent would be too costly for the benefits secured. It would not be possible to install four 10-inch guns—the weights of guns, turrets, etc., would be prohibitive. The money would give more fighting value if applied to entirely new ships of the dreadnought class.—ED.]

### Death of Prof. Amos E. Dolbear

Prof. Dolbear died at Bedford, Mass., on February 3rd, at the age of seventy-four. He was widely known as an inventor of electrical devices. Perhaps his investigations in wireless telegraphy brought him more into public prominence than any other, but the result was an infringement suit in which he unsuccessfully sought to restrain Marconi from continuing his experiments.

Prof. Dolbear took the degree of B.A. at Wesleyan University in 1866, and the degrees of M.A. and M.E. at the University of Michigan in 1867. From 1866 to 1867 he was instructor in Chemistry at the University of Michigan. Then he occupied the chair of Assistant Professor of Natural History at the University of Kentucky from 1867 to 1868. From 1868 to 1874 he was Professor of Physics and Chemistry at Bethany, W. Va. From 1874 to the time of his death he was Professor of Physics and Astronomy at Tufts College. His scientific investigations included the study of light and electrical phenomena, the properties of the ether, magnetic telephony, static telephony, heavy current ammeters, cables for telegraphic and telephonic work, wireless telegraphy, and the properties of matter.

### Comet B 1910

Prof. Pidoux of Geneva Observatory, Switzerland, has cabled to Harvard College Observatory stating that he discovered a comet on February 20th in R. A. 0 h. 16 min. 22.1 sec. and Dec. +7 deg. 50 min. and 41 sec. The daily motion in right ascension was —32 min. 24 sec. and in declination —24 min. The new comet is not very far from Halley's comet. According to the corrected ephemeris of Crommelin the position of Halley's comet at the time was R. A. 0 h. 41 min. 29 sec. and Dec. +7 deg. [illegible] min.

According to Electrical Engineering, a definite proposal has been put forward for the construction of a tunnel between Denmark and Sweden, starting at Copenhagen and connecting up with Malone. Connection would be made on the way with the small islands of Amager and Saltholm, and the electric trains which it is proposed to work through the tunnel would run on the surface on these islands in order to reduce the underground journey as much as possible. If the scheme is carried out it is estimated that the trip could be made in 1½ hour.

# OSTRICH FARMING AS AN INDUSTRY

BY NEWTON FOREST

Does ostrich farming pay? The question is asked by almost everyone who visits an ostrich farm The answer is that when an acre of alfalfa will furnish a home for four birds with food enough to maintain them throughout the year when an ostrich will yield annually about two pounds of feathers with an average value of $20 a pound and from thirty six to ninety eggs which may be used for incubation or may furnish food at the rate of nearly four pounds to the egg if the owner does not wish to increase his troop ostrich farming does pay and pays well

There is nothing very lovable about an ostrich as there usually is about other domestic animals But however lacking in personal charm it may be the big bird is a money producer A head of cattle eats sixty five pounds of alfalfa in a day an ostrich ten pounds This head of cattle at five years old is worth $10 and an ostrich at that age is worth $2?0 There is nothing to the cattle but meat At ten months the ostrich will produce $10 worth of feathers and thereafter from $35 to $1?0 worth of feathers annually for a long period of years Though an ostrich is matured at the age of five and is reproducing its average life is about that of a human being The bird does not begin to decline until it is fifty years old Many however produce fine plumage at the age of seventy five

There is as much difference in the breed of ostriches as there is in any other animal Some of the California and Arizona male birds are rated at as high as $?000 each but ordinarily the value averages about $400 for a one year old bird and about $100 for a chick Some of the cocks weigh as much as ?00 pounds and stand over ten feet high

It has of late years been found that a great deal of money can be made in ostrich farming Especially so where alfalfa or lucern can be raised on irrigated lands In the Salt River Valley in Arizona there are about 20 000 acres of rich land soon to be made richer and more productive through immense irrigation works on which the United States is spending $6 000 000 Such a climate is an ideal one for ostrich farming as the farms in that locality have already proven by their successful operations While the birds thrive best in a warm dry climate they can be grown in any of the southern States and Territories of this country In a moist climate however they would have to be protected from cold and rain

It is only a little more than two decades ago since the first ostriches were brought into the United States with the serious purpose of attempting their culture here Before that time the only birds seen in this country had been adjuncts to circuses To-day exclusive of those in zoos there are some four thousand birds on the American continent. Probably half of this number are the progeny of a single pair owned in Arizona in 1891

The female ostrich matures much earlier than the cock beginning to lay fertile eggs when she is about three and a half years old The nest is nothing more or less than a hole scratched in the ground which is done by the male bird At first the hen may not take to the nest but may lay her first eggs on the ground whereupon the male will roll them into the nest Generally after the male has put three or four eggs into the nest the female will take to it She will then lay an egg every other day until about sixteen eggs have appeared in the nest An ostrich egg is nearly eight inches long and about six inches in diameter It makes a good omelet and is excellent when scrambled One egg will make as much omelet as three dozen hens eggs A full-grown bird has been known to produce over three hundred pounds of egg food in a year

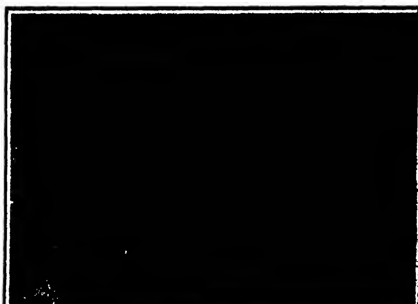
An annual increase of about fifty per cent of a flock is secured mainly through the use of incubators, though on every farm a few paddocks are maintained each for the sole occupancy of a pair of birds Three times a year the hen begins to lay She does most of her setting during the daytime the male bird attending to that part of the household duties at night He will usually go on the nest about five o clock in the evening and remain there until eight o clock next morning It is thought that the color of the sexes has something to do with developing these instincts The male being black is not so easily seen at night and the female being drab or nearly the color of sand cannot be readily observed on the nest in daytime The male usually begins to sit three or four days before the hen stops laying If the weather is cold during the laying period the male will often be found covering the eggs at intervals during the night to prevent them from becoming chilled The birds are also very watchful in the warmest season to prevent the eggs from becoming superheated by the sun The birds do this by resting on their ankle joints and spreading their wings umbrella wise over the nest As is usually the case with all eggs in a dry climate the shell of an ostrich egg becomes dry and hard It is therefore very difficult for the chick to break through When the time arrives for the liberation of the young they are heard to chirp and to move in the shell. The parent bird seems to understand the situation, and will often crack the shells with his breastbone, sometimes taking the young by the head and pulling it out of the shell Sometimes four or five days elapse between the hatching of the first and the last egg During this time one of the parent birds sticks to the nest while the other takes care of the chicks However on a well regulated ostrich farm the farmer assists the birds in hatching by cracking the eggs with a small hammer and putting the unhatched eggs into an incubator

The chicks appear to be all eyes and necks when they first come out of the shells yet their bodies are as large as those of full-grown hens They are as fussy and as soft as a day-old chicken but far more stupid For the first week of their existance nothing but gravel is given the young ostriches Then they are turned into small pens in the alfalfa lots where they are to eat alfalfa for the rest of their lives.

Plucking is the general term by which the harvesting of feathers is known The term might lead one to believe that the feathers are pulled out. This is not the case however for that would injure the bird. The plumes are snipped off with shears close to the flesh The quills that are left soon die and drop out after which new feathers begin to sprout There are twenty five long white plumes on each wing of the cock bird The rest of the plumage is black on the male and of a grayish color on the female Gathering the feathers is no easy task. This work has to be done with great care for a kick from one of the powerful legs of the bird is enough to disable a man for life or even kill him outright

At the plucking time the birds are driven into individual plucking boxes and a loose bag slipped over their heads, which tends to keep them quiet A cock bird will roar mournfully while being plucked although the operation is absolutely painless After he has been stripped of his plumage he is about as ugly a sight as one could behold

The first experiment of ostrich farming in this country was made by an Englishman who imported his birds from Africa and paid as high as $1 200 a pair for them As in nearly every venture of this character, the originator of the scheme did not make a fortune out of it But the wise and daring investors who followed in his footsteps are now congratulating themselves. They are reaping the harvest no doubt dreamed of by the starter of the industry in Cali-



A male chick just hatched by an incubator.

OSTRICH FARMING AS AN INDUSTRY.

[illegible] it is almost impossible for milliners to meet the demand for high-grade feathers, and if they were dependent solely on the stock imported from Africa, it would be quite out of the question. But so flourishing has been the American ostrich-farming industry that a large part of the supply is now home product. The feathers produced in the United States are just as fine and in some cases much superior to those grown in Africa.

[illegible]

operation is done by French girls, and the skill with which this work is carried on is marvelous. To each flue on a long plume is tied another in such a way that the joint is invisible. Some plumes treated in this manner have been priced at $1 000

### Elektron Metal: a New Light Weight Alloy

At the International Aeronautical Exposition in Frankfort a Griesheim firm exhibited a new and patented alloy or series of alloys under the name elektron metal. These alloys possess great strength united to exceedingly low specific gravity and hence appear to be the material of the future for various structural purposes. Aluminium and its alloys the lightest metals now used in practice, are fifty per cent heavier than elektron metal and far inferior to it in strength and tenacity. The new alloys are composed chiefly of magnesium the rather inferior structural qualities of which metal have been very greatly improved by additions of various other metals. The alloys vary in specific gravity from 1 75 to 2 0 possess great strength tenacity and elasticity and are easily worked. They have a clear metallic ring and when polished a beautiful silvery luster. Their resistance to atmospheric influences satisfies every practical requirement, as they become covered with a protective film of oxide when exposed to the air. Even in the form of castings they show a tractile strength up to more than 25 000 pounds per square inch and an extensibility up to 5 per cent. By pressing rolling and drawing, the tractile strength can be increased to very nearly 50 000 pounds per square inch and the extensibility to 15 per cent, without producing any appreciable increase in specific gravity. The properties of the alloy can be varied within wide limits by selecting the nature and proportions of the metals which are added to the magnesium.

The field of usefulness of the new material, therefore, is very extensive. Its strength and lightness make it especially valuable for the construction of airships and aeroplanes, but it may also be employed with advantage in the construction of automobiles motors, and machines and instruments of every kind. It is so much stronger and lighter than aluminium and its alloys that 60 pounds of it may be substituted for 100 pounds of those materials. For example in a Zeppelin airship having an aluminium frame weighing 12 000 pounds 5 000 pounds weight could be saved without any reduction of strength by the substitution of elektron metal. It would then be possible to carry more fuel and ballast increasing the radius of action more passengers or larger and more powerful motors. It may even be found possible to diminish the dimensions of the airship and the cost of operating it by an extensive employment of the new material. Similar advantages may be expected in automobile construction. A large automobile motor for example contains about 450 pounds of aluminium which could be replaced by 275 pounds of elektron metal. At the exposition the new material was shown both cast and wrought into a great variety of forms.—Umschau

An ostrich-drawn cart.

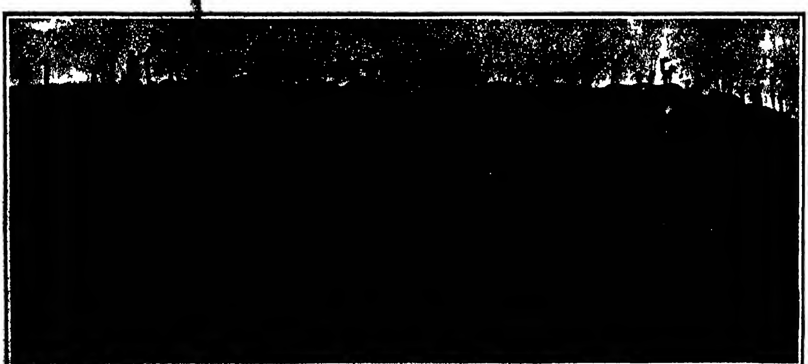
A pair of birds and their eggs

The business of ostrich farming has long become a science before it was introduced into this country. In South Africa there are all manner of laws to protect the business. There is a governmental ostrich doctor whose particular duty it is to study the diseases peculiar to such birds. There is also an ostrich breeding association where are recorded the pedigrees of the finer birds. Some of the farmers have so improved their stock that their ostrich chicks bring from $500 to $1 000 each and many of the most noted cock birds are priced at $7 000

Port Elizabeth in South Africa is the chief ostrich feather port of the world. In that vicinity there are nearly a half million birds now in captivity. The feathers from these birds sell from $10 to $150 a pound and the industry of this one port alone amounts to some $15 000 000 a year

There are some districts that produce better feathers than others. The Oudtshoorn feather reaches twenty [illegible] inches in length, the [illegible]

The consumption of pulp wood during 1906 by 251 pulp mills in the United States amounted according to a preliminary report of the Bureau of the Census to 3 346 106 cords of wood which furnished 2 118 947 tons of pulp. Nearly 1½ million cords of domestic and over 670,000 cords of imported spruce were consumed. Next in order is domestic hemlock of which 569 173 cords were converted into pulp. More than 300 000 cords of poplar were cut last year mostly from domestic timber. The remainder of the timber about 19 per cent, was chiefly supplied by pine cottonwood, and balsam



The value of the 110 birds in this picture is at least $50,000.

OSTRICH FARMING AS AN INDUSTRY

## THE HEAVENS IN MARCH

BY HENRY NORRIS RUSSELL, PH.D.

AS the year advances, there is a temporary break in the series of cometary phenomena which make the first half of 1910 so noteworthy. Innes's comet, which was so fine an object at the end of January, came almost to rest among the stars early in February, moving almost straight away from the earth and rapidly losing brightness. By this time it is unobservable, behind the sun and some distance north of the ecliptic. In another month or so it should be seen in the morning sky, but only with telescopic aid.

The determination of its orbit has apparently presented unusual difficulties. In order to calculate a comet's orbit, we must first have accurate observations of its position. Such observations are usually made by measuring with the telescope the distance and direction of the comet (or equivalent quantities) from some star whose place in the sky is known from previous observations, taking care to note the time at which these measures were made. In the present case the comet was at first visible only in daylight, when no suitable "comparison stars" could be seen. Its position in the sky had therefore to be found by means of the readings of the graduated circles attached to the telescope, and these are far inferior in accuracy to measures of the former kind.

It is not therefore surprising that the preliminary orbits calculated from these rough observations differ widely among themselves. When the comet reappears in the morning sky, and can be accurately observed, the comparison of the results with the few accurate observations made in January and February will set tle the question.

Halley's comet is also out of sight for the present—behind the sun, or nearly so, and about 175 million miles away. It may still be observed telescopically low in the west in the early evening for a few days early in the month, but it cannot be seen in the morning sky until April is well begun, when it will reappear, much nearer us, and probably far brighter than when it vanished in the twilight.

We must therefore for the time being turn our attention mainly to the stars, and among them we will find much to occupy us while we wait for the comet to reappear. Let us begin right overhead with the constellation Gemini. Its two principal stars, Castor and Pollux, identify it at once, for nowhere in our skies are two equally bright stars as near neighbors. The roughly parallel lines of stars which run southwest from these and terminate in the stars $\gamma$ and $\eta$ are also easy to identify if once learned.

Castor itself is a fine object with even a small telescope, showing double with a power of fifty diameters. The two components, one about twice as bright as the other, revolve about one another with a period of perhaps 400 years. The faint star which lies about twelve times as far from them as they are from one another is moving with them among the other stars, and is probably also in very slow revolution about them, but, if so, must take more than ten thousand years to complete a single circuit. The star $\delta$ is also a fine double. Close by to the eastward is Cancer, with no bright stars but one interesting cluster, visible clearly to the naked eye, and resolved into its separate stars by a field glass. This spot of light, known as Praesepe (the Beehive), is marked on the map.

Auriga, which lies in the Milky Way, northwest of the zenith, is one of the finest constellations in the sky. The figure of the charioteer kneeling in his chariot forms our initial letter. The most northerly bright star of the constellation, $\delta$, is in his head, $\beta$ is in his right arm, and the brilliant yellow star Capella ($\alpha$) marks the Goat which he is supposed to hold in his left arm, while the three smaller stars just below it are called the kids—an armful indeed! Farther south $\theta$ is in his right knee, and $\iota$ in his left foot, uncomfortably near the tip of one of the Bull's horns ($\beta$ Tauri).

Capella is, next to Sirius, the brightest star in the part of the skies which we can see—according to the data of the Nautical Almanac. Arcturus and Vega are however very nearly its equal in brightness, and the three stars differ so widely in color that different observers, whose eyes were unequally sensitive to light of different colors, might easily disagree as to their relative rank. Well down in the west are Orion and his neighbors, Canis Major on the left and Taurus on the right. Mars passes through the latter constellation during the month, and fairly rivals Aldebaran in color and brightness. Perseus and Andromeda are in the northwest—the latter partly set—and Cassiopeia farther to the left.

Due south we see Procyon, with the few faint attendants which are supposed to resemble the Little Dog, high up near the meridian, and part of the great constellation Argo low on the horizon. Farther east, on a level with Procyon, a small but conspicuous group marks the head of the great serpent Hydra, whose body may be followed, past the lonely red star Alphard, down to the southeastern horizon. To the left are Corvus and Crater, and then Virgo, made unusually brilliant by the presence of Jupiter, which is just below the notable double star $\gamma$. Higher up is Leo, one of the finer constellations, recognized at once by the "Sickle," at the end of whose handle is the first-magnitude star Regulus.

Farther west, near the horizon, Arcturus shines brilliantly, far surpassing his neighbors in Boötes. Above and on the left is the familiar and gigantic form of the Great Bear. Within the curve of the Bear's tail (the Dipper handle) are the Hunting Dogs which pursue her on an endless chase around the pole. They have but a single bright star, but this is a fine double, worth looking at if one has a telescope magnifying twenty times or more.

The group of small stars known as Berenice's Hair, to the southward, is a good example of a star cluster so coarse that it can be resolved by the naked eye, but yet composed of stars faint enough, and near enough together, to produce almost the impression of a nebula at a hasty glance, while closer scrutiny shows the individual components. Draco, coming up on the right of the pole, Ursa Minor, inclosed within its sweep; and Cepheus, low in the north, complete our survey.

### THE PLANETS.

Mercury is morning star all through March, but, being south of the sun, is not well observable in these latitudes. He may perhaps be seen early in the month, but only with difficulty, as he rises but three-quarters of an hour before the sun.

Venus is likewise a morning star, and, unlike Mercury, is very conspicuous.

She reaches her greatest brightness on the 18th. At this time she appears, with a magnifying power of fifty diameters, just as the crescent moon some five days old does to the naked eye, except that her surface is free from perceptible markings, and uniformly white. She rises about 4 A. M. and is the principal ornament of the morning sky. Indeed, there is no difficulty about seeing her in broad daylight—if the sky is really clear—except that of knowing where to look for her. On the morning of the 16th the crescent moon will be a good guide, as Venus will lie about five or six degrees nearer the sun, and about two degrees above the line joining them.

Mars is still an evening star, but is steadily losing brightness. His distance from us increases from 145 to 170 million miles during the month, and he moves eastward among the stars through Taurus, keeping well ahead of the sun, so that he remains in sight till after 11 P. M.

Jupiter is in opposition on the 31st, and is visible all night long. He is a splendid object to the naked eye, and a fascinating one in even the smallest telescope. His four large satellites can be seen without difficulty, unless indeed some of them should be behind or in front of the planet. In the latter case their shadows can be seen, as black dots on Jupiter's surface, with more powerful instruments, and afford one of the most interesting of celestial spectacles as they transit across his disk.

The elliptical form of the planet due to his rapid rotation, and the dark belts which cross his disk, parallel to his equator, can also be seen with a small instrument. The four other satellites, discovered in recent years, are observable only with a few of the largest telescopes.

Saturn is an evening star, setting about 8 P. M. In the middle of the month Uranus is in Sagittarius, rising about 3:30 A. M. at the same date. Neptune is well observable in Gemini, his position on the 15th being R. A. 7 h. 11 m. 35 s., Dec. 21 deg. 44 min. north, and his apparent motion very slow. To identify him, however, one needs either a detailed star map or a telescope large enough to show his disk, that is, six inches or so in aperture.

The moon is in her last quarter at 3 A. M. on the 4th, is new at 7 A. M. on the 11th, in her first quarter at 10 P. M. on the 17th, and is full at 3 P. M. on the 25th. She is nearest us on the 12th, and farthest off on the 28th. In her circuit around the sky she passes near Uranus on the 7th, Venus on the 8th, Mercury on the 9th, Saturn on the 13th, Mars on the 16th, Neptune on the 19th, and Jupiter early on the morning of the 26th—only the last conjunction being at all close.

At 7 A. M. on March 21st the sun crosses the celestial equator, passing over the point in the heavens called the vernal equinox, or "first point of Aries," and in almanac language "Spring commences."

Gilding Glass or Porcelain.—Prepare a mixture of 900 parts of lavender oil, 100 parts of gold chloride, 5 parts of bismuth subnitrate, and 56 parts of chrome soap. After application, leave the mass to dry and bake the article in a muffle furnace. A brilliant gilding will be produced without further [illegible].

# THE BULLET'S FLIGHT*

## SOME NEWLY DISCOVERED ERRORS IN TARGET SHOOTING

In the face of many excuses, it is a recognized fact that the bullet from a rifle seldom strikes the target where the marksman would like to have it strike. The constant endeavor for years, in all countries, has been to perfect the rifle and reduce its errors at the target. Unlimited time and money have been expended in these efforts. According to the author of the book which lies before us, an author who speaks with a conviction gained from years of patient investigation the innumerable causes of inaccurate rifle shooting, many of which have been known for a long time, may be divided into two great classes: first, those inherent in the rifle and its ammunition, and secondly, those which are external to it.

His experimenting and hence his discussion deals exclusively with the errors adherent to the rifle and ammunition, and does not consider any of those belonging to the second class, such as air currents, personal elements of the shooter, humidity of the air, or any error in aiming the rifle. Years of careful machine-rest shooting and the experience of thoughtful riflemen point clearly to the fact that, when all the elements of the second class are excluded, the rifle and its ammunition produce a regular and ever-present error at the target which has not yet been overcome. To determine the nature of that error is the author's primary purpose.

The cause of this ever spreading of shots he has experimentally disclosed, with the result that the rifleman knows better than he ever did before, the defects of rifle and bullets. The book teaches us how to eliminate the errors of the rifle and its ammunition, and to know which elements of the cause for such errors cannot be overcome by human skill, thus allowing us to proceed intelligently rather than under old methods of guesswork experiments.

The method and apparatus to bring out these hither to undiscovered errors are fully set forth, illustrated, and explained. The system of investigation adopted was based on the principle of exclusion, that is, the personal element, movement of the air, mirage, and faulty aiming were eliminated. Covering as it does the work of years, the book is commendably exhaustive.

During 1901 a suitable machine rest, differing materially from anything before produced, was made as here illustrated (Fig 1). It was built of concrete, and was permanently rigid. Upon it a bronze V three feet long was securely bolted. The barrel of the rifle, stripped of its normal action and wooden stock, was mounted in aluminium rings, one for the muzzle and one at breech, and, thus surrounded, was held in its normal position in the bronze V, which was accurately machined. A concentric action, as shown by illustration (Fig. 2), took the place of the normal rifle action, completing this part of the outfit. The line of fire remained the same from day to day and from year to year.

Between the rifle's muzzle and target, paper screens were placed, through which the bullet passed in its flight. A perpendicular line through the center of each screen, by the aid of telescope and cross hairs, was brought into exact line of the V rest, which was also the line of fire of the rifle barrel which lay upon it. This arrangement of lines and screens enabled the author to follow the course of each bullet, and the screens were spaced at distances along the range to match the experiment in hand. A distance of three feet apart was sufficient for testing some of the curves which the bullet made, but in many experiments it was found necessary to place the screens from six to three inches apart to register the bullet's motion. Day by day facts were accumulated, and at the end of several years the author could so place these screens that any desired information respecting the bullet's motions could be expeditiously obtained, one irregularity after another being eliminated to that end.

As is often found to be the case in all scientific experiments, preconceived ideas of the bullet's action proved to be more or less incorrect, and the strongest fixed idea of all, the one to which it seemed all conclusions must be made to bend, was found to be absolutely incorrect. This idea, that the bullet during its passage through the rifle must and did fly in a straight line with the bore, and that afterward it changed its direction to fly away from the mark, held the author back from the real fact for years. Screens placed at one, two, or three feet from the muzzle showed indisputably that an unbalanced bullet left the line of fire, or line of the bore, immediately upon its exit therefrom, and the cause of this was a very astounding discovery to make.

It is easily understood that the center of gravity of an unbalanced bullet is not in its center of form, and therefore not in center of the rifle bore. Due to the twist in all modern rifles, this unbalanced bullet rotates during its passage to the muzzle and carries its center of gravity in a spiral around the straight line forming the center of the bore, and also carries its center of gravity around the center of form of the bullet itself. In mechanics and especially in ballistics the course through which a body moves is the line in which its center of gravity travels. Hence the unbalanced bullet (all bullets being more or less unbalanced) travels in a spiral through the straight rifled bore, compelled to take this spiral course by the solid walls formed by the internal surface of the barrel.

When the projectile is liberated at the muzzle, no longer forced to make a spiral flight, it immediately takes up a straight flight, which it must do according to the fixed laws of inertia. This straight line, however, is a continuation of the flight which the bullet was making as it left the muzzle, not the line of bore, but a tangent to the spiral which the projectile described in the bore as represented (though grossly exaggerated, by the spiral s s and its tangent a or c c in Fig 3.

Fig 3 exaggerates and makes clear how the center of gravity of an unbalanced bullet moves in a spiral form within the bore, but how when liberated at the muzzle, it takes a straight flight, as represented by the tangent at the right extremity of the spiral in the direction of a. No possible power at the muzzle could make it take the direction of bore as represented by d d, without disintegrating the bullet. Thus the bullet, instead of flying straight in the rifle bore as every one supposed, and making some change in its direction afterward, in reality flies in a spiral during its passage to the muzzle, and does not change its direction at the muzzle, because there is nothing there so to change it. This is the long-searched for cause of error at the target.

The presence of this error, called the "X error" by the author, was clearly demonstrated in screen shooting by E A Leopold of Norristown, Pa, a number of years ago, and the apparent change of direction in the flight of a bullet at the muzzle was known in an indefinite manner to various riflemen. Their attempts to overcome it, and the theory upon which these attempts were

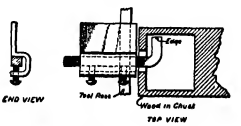
# Handy Man's Workshop

## TOOL-HOLDING DEVICE FOR WOOD TURNING

BY CHAUNCEY W. NIPMAN

Those who use a wood lathe find frequent occasion to make special tools for difficult or unusual work, and when the tool is so shaped that the cutting edge is at right angles to the shank, great annoyance is experienced in holding the tool to the work, and keeping it from turning in the hand Recently I had



TOOL-HOLDING DEVICE FOR WOOD TURNING

a piece of work similar to that shown in the drawing and after many expedients had failed to give complete satisfaction I developed the device illustrated It is made of heavy sheet steel (the heaviest I could work easily) and provided with two set-screws, as shown, to allow it to be moved along the chisel as desired, and for the insertion of new chisels As illustrated, the flat portion lies on the tool rest, and this absolutely prevents the turning of the tool By its use I was able to reach with ease the most inaccessible corners.

## ELECTRIC INCUBATORS AND BROODERS.

BY FREDERICK E. WARD

The advantages of an electrically heated incubator over those making use of kerosene lamps and the like are so great, that as rapidly as cheap reliable power service becomes extended throughout the country, the hatching of eggs by electricity bids fair to displace all other methods.

An electric incubator can be built at home by anybody who can make a wooden box and connect up ordinary incandescent lamps. Such a machine has not only the merit of being low in first cost, but of having nothing about it to wear out, and of being capable of giving perfect results with very little attention on the part of the operator

The photographs show the first incubator built by the author, while the drawings give details of construction drawn to scale, for a similar machine of fifty eggs capacity Briefly it consists of an outer and an inner wooden box, having the space between them packed with wool or other heat retaining material The eggs are placed in the inner box, which is warmed with incandescent lamps controlled by a thermostat

The boxes should be made of well-seasoned lumber about ½ inch thick Old soap boxes furnish good material for the purpose For a fifty-egg machine the inner box needs to be 11 inches wide, 17 inches long, and 11 inches deep, all inside measurements This box is to be left without any top or bottom except a slatted bottom which is to be put in half way down thus dividing the box into an upper and a lower compartment of equal depth On top of the slats a double thickness of woolen blanket should be tacked, to support the eggs, as shown in Fig 1

Eight electric lamps are required for the heating units These are best mounted in porcelain receptacles as shown, four lamps in each compartment near its top For 110-volt circuits use ordinary 16-candle-power carbon filament lamps made for 230 volts, and connect them as shown in the diagram, where *REG* means regulator, or thermostat and *SS* are snap switches to be placed on the outside, as shown in one of the photographs.

It is hardly worth while to make a thermostat at home when one suitable for the purpose can be bought from a dealer in electrical supplies for about seventy-five cents, but it is not a difficult job for anybody who takes pleasure in doing such work Fig. 2 shows a simple form of thermostat attached directly to the inside of the egg chamber The essential part consists of two strips of metal riveted together as shown in the top view at *A* Zinc and steel (or iron) make the most effective combination, brass and steel (or iron) come next The strips should be about 1/32 inch thick, 8 inches long, 1 inch wide at the large end and 3/8 inch at the narrow end They may be fastened together with fifteen or twenty small rivets, or by soldering them all around the edges The two metals thus joined tend to curl and uncurl with changes in temperature, by reason of their different rates of expansion The large end should be clamped to a block, *B*, as shown, and a contact screw should be provided at *C*, with a stiff wire, *D*, attached to serve as a screwdriver for adjustment from the outside It is highly important that the tip of the screw *C* and the spot on the zinc (or brass) strip be protected by pieces of platinum soldered on, or the electric arc which appears between them will soon destroy them If the thermostat be purchased as advised, it must be mounted in such a position that the adjusting screw can be reached by a screwdriver or wire passing in from the outside through small holes in the boxes.

The inner and outer boxes are to be joined at the bottom by a passageway or tunnel three inches high, forming a doorway through which chicks may enter the brooding compartment under the egg chamber The inner and outer boxes are to be joined near the top by three or four half inch tubes for ventilation as shown at *V*, Fig 2

The top of the egg chamber is best covered over with a pane of glass, on top of which is laid a small pillow or several thicknesses of folded blanket.

Next in importance to the thermostat comes the choice of a thermometer and its proper location in

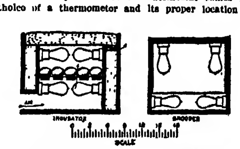


Fig 1.—CONSTRUCTIONAL DETAILS AND WIRING DIAGRAM OF THE INCUBATOR AND BROODER.

the egg chamber, where the bulb should occupy a central position rather than one near a corner It is not necessary to buy an expensive instrument in order to get accuracy, an ordinary ten-cent thermometer can be made to serve the purpose very well provided that its scale be properly corrected or "calibrated" This may be easily accomplished by taking advantage of the fact that the internal temperature of a normal, healthy person is just a trifle over 98 deg Tie a thread around the tube at the place marked 98 deg on the scale, and remove the tube from the scale, to which it is usually attached by two bits of wire. Place the bulb under the tongue at the side of the mouth and hold it until the mercury column does not rise any higher By observing with a mirror it will then be possible to determine quite accurately how much in error the marking on the scale may be, and due allowance for this can then be made by assuming that the same error is present at the 104-deg. mark, which is the temperature of incubation.

The machine must be run a few days before any eggs are put in, to give time for carefully adjusting the thermostat When the latter is once set right it will automatically maintain the heat at the desired point by "winking" the lamps on and off. With all eight lamps in use, the apparatus as described is capable of maintaining a temperature of 104 deg. in the egg chamber when the room temperature is only 40 deg. If used in a warmer room, one pair of the lamps in the lower compartment may be turned off by means of the snap switch

Each pair of 230-volt 16-candle-power carbon lamps, connected in series as shown, will, when used on a 110-volt circuit, burn with a dull red glow scarcely visible in daylight, and with a power consumption of 5½ watts. A fifty-egg machine operated in a room where the temperature is 65 deg. consumes about 16 watts, making a total for 22 days of about 8 kilowatt hours, which, where the rate is 10 cents, costs 80 cents. This cost looks high at first sight, but it is materially lower than that of a kerosene-burning machine if one stops to consider the saving in interest on first investment,

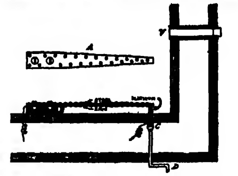

Fig 2.—METHOD OF APPLYING THE THERMOSTAT.

the saving in oil, the absence of depreciation and repair bills, and the saving in labor of attendance.

In the practical operation of the incubator, the following points should be borne in mind

The eggs need to be turned partly over every day A good way to do this is to take out the row of five eggs at the left hand end, roll the remaining ones toward the left, and replace the five at the right-hand end This progressive movement serves also to even up the different times of hatching that might result from some eggs remaining in warmer spots than others

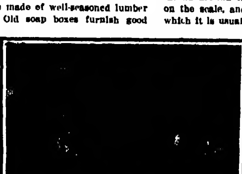
Increasing ventilation is required as incubation progresses Practically no air is needed the first two weeks, and all ventilating tubes and the door to the lower compartment may be kept closed with considerable economy in power During the third week, and especially when the hatch is due, plenty of air must be allowed to filter up through the eggs, as shown by the arrows in Fig 1

No moisture is required during the first week Thereafter it is best to keep a small pan of water in the lower compartment and a small glassful in the egg chamber These serve to prevent excessive evaporation of the eggs by too dry air

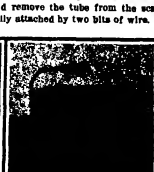
The newly hatched chicks should not be taken out or fed until they are 24 hours old After this they may be kept in the lower compartment for a time, provided all four lamps be kept burning. As soon as convenient, however, they should be transferred to an electric brooder, two forms of which will now be described

The first and simpler form, suitable for use only in a well warmed room, is shown in one of the photographs. It consists of a small wooden table carrying on its under side four lamps, and surrounded by a fringe made by slitting a piece of old blanket. For use on the ground or where the floor is not warm, bottom heat must be provided as shown in Fig. 1 Forty chicks can be accommodated by such a brooder having the following dimensions Top, 14 by 20 inches, supported by legs 8 inches long. Bottom box of wood, 14 by 20 inches outside, 3 inches deep inside. Box-cover of tin 14 by 20 inches, protected on top by a sheet of paper and a sprinkling of sand Four lamps are required in the upper part, one near each corner, and two in the bottom heater It will be observed in the diagram of connections that the latter lamps are connected in parallel and not in series, which causes them to burn more brightly The power consumption is 33 watts, or about twice what is required for hatching. No thermostat or thermometer is needed for the brooder It will not get too warm if the current is left on all the time.

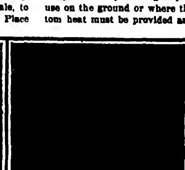
Where any form of bottom heater, such as that here described, is used it is [illegible] with the floor or to [illegible]



THE BROODER WITHOUT BOTTOM HEATER.



INCUBATOR WITH BROODING COMPARTMENT OPEN.



PLAN VIEW WITH COVER REMOVED.

of which the chicks may get up on the raised platform.

The following bill gives a list of all materials needed and their present retail prices.

| | |
|---|---|
| For the Incubater | |
| 8 220-volt 16-candle-power carbon lamps | $1.60 |
| 8 porcelain receptacles | .48 |
| 1 thermostat | .75 |
| 1 thermometer | .10 |
| 2 single-pole snap switches | .30 |
| 1 piece 12 x 18 window glass | .20 |
| Lumber, etc. | .15 |
| Total | $3.58 |
| For the Brooder. | |
| 6 220-volt 16-candle-power carbon lamps | $1.20 |
| 6 porcelain receptacles | .36 |
| 1 sheet 14 x 20 tin | .15 |
| Lumber, etc. | 65 |
| Total | $1 76 |

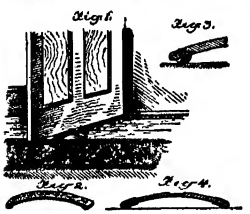
The foregoing bill does not include the shaded lamp and fixtures shown on the outside of the incubator in Figs. 1 and 2 An ordinary 4-candle-power lamp so mounted is a convenience, but not in any way essential.

## CONVENIENT DOOR HOLDER.

BY D. PENNINGTON

A convenient door holder may be made from a barrel hoop, as shown in the accompanying illustrations, by cutting a piece about eight inches long and inserting a rubber-head tack (such as used in the plumbing trade) at each end, on the under side, as shown in Fig 3 Two such tacks are also placed on upper face, spaced apart sufficiently to allow the bottom of the door to fit between them. The arched shape of the hoop will give sufficient friction between the door and floor to hold the door in any desired position

If rubber-head tacks are not available the ends may be covered with some soft material such as carpet and tacked thereto. In place of tacks, a notch may be cut in the barrel hoop equal to the thickness of the door, as shown in Fig. 4 of the illustration. The



HOME-MADE DOOR-SECURING DEVICE.

center of a barrel stave may be used instead of a hoop by cutting it to about the same width as the hoop

## BORING HOLES IN GLASS.

BY GEORGE J MURDOCK.

Glass is universally conceded to be exceedingly difficult to work when cold, yet its fragile nature often calls for means of repair It is also desirable sometimes to drill large holes in glass plate, or through a glass column, which is not an easy thing to do with any facilities hitherto developed for such work.

It is well known that turpentine applied to a small drill will enable one to drill through a piece of glass by persistent application and frequent grindings of the drill. This hole will often taper from a larger diameter at the top to a smaller one at the bottom, and besides it is quite impossible to drill two holes of the same size with the same drill Instrument work of certain classes would be made better also if it were possible to tap threads in the glass of which the base or other parts are composed In the opinion of the writer the best fluid to be applied to the glass so that the tool will take hold is that of the formula given below. It has been developed after many experiments with different mixtures, and will be found to be superior to anything heretofore known With a bastard file wet with it, a piece of plate glass may be put into a stop and filed like wood; any other cut of file may be used, but where there is much glass to remove, the coarser the file the better.

For drilling small holes, a brass tube of the diameter of the hole wished is better than a drill. The tube should be made smooth on the end that is to come in contact with the glass, and charged with carborundum powder, or what is better, diamond dust. In watching the hole a piece of wood having a hole drilled in it of the size of the brass tube should be cemented to the glass, the hole being located over the spot where the [illegible] is to be made. A hole should be made in the side of the tube by filing into it with a round file, and it may be turned either by a drill press or by one of the small, geared, hand drill-stocks used for small drills. With a small brush dipped into the solution as herein given wipe the hole so that a little of the mixture will run down inside the tube, and onto the glass where the hole is being made, and the tube will be found to enter the glass with surprising ease.

If it is desired to have the edge of the hole sharp where the tube comes through, cement a small piece of

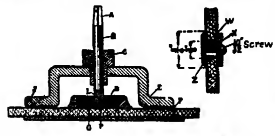


Fig. 1.—APPARATUS FOR BORING LARGE HOLES IN GLASS. Fig 2.—METHOD OF REPAIRING CRACKED PLATE GLASS.

glass to the under side of the plate being bored, and when the tube is through, continue the boring until it has entered the lower plate slightly Glass cut with the diamond will often break unevenly, and fail to fit a window sash, circles cut out for the dials of instruments of the clock class, circles for static electric machines, glass covers for galvanometers, ammeters, and many other instruments are often thrown away, when a touch with a file wet with this solution would save them It is especially recommended to glaziers to remove the sharp edges of the glass cut with the diamond, which often cut the hands. For boring large holes in plate glass the jig shown in the sectional view, Fig 1, is very handy, in fact almost essential if correct results are required It can be easily modified to hold the cutter for boring circular work, such as glass columns or concave surfaces, where circumstances require such variation The frame is an iron casting having feet J, and is bored out to receive a steel bushing C, which may be hardened after a central hole is made to receive the shank B of the cutter bar The top of the cutter bar or shaft is squared at A so that a bit stock may hold it, or it may be held by the chuck of a drill press. The bottom has a flange and a pilot L, which fits in the hole of a small emery wheel G of the kind used by toolmakers on universal grinding machines for lapping out small holes.

The lead bushing in the wheel should be cut out on the side that is to do the boring, and the pilot L must not go entirely through the wheel, but be cut at least ⅛ of an inch short of the wheel thickness The wheel may now be cemented to the cutter shaft by heating it, and also the wheel slightly, so as to melt some gum shellac which has been sprinkled on the top side of the wheel. After it is cold mix up a stiff paste of liquid glue and emery of about the same grade as the wheel, and fill the bottom of the hole P even with the wheel In drying it will shrink slightly and the paste may be applied again, and until the surface is flush with the side of the wheel.

The feet J of the frame have thin rubber F (known in the stores as "rubber dam") cemented to their under sides with bicycle tire cement, so that when placed on the glass the jig will not slip around, but can be easily held in any desired location

The place where the hole is to be made having been ascertained, a ring of putty D is stuck to the glass to form a cup, and after the wheel shaft is inserted in the bushing, the apparatus is placed with the face of the wheel over the spot to be bored, with the feet J resting on the glass Before beginning operations a piece of double-thick window glass H is cemented with French copal varnish to the under side of the plate to be bored.

The formula for the fluid to be applied to the tools is as follows

| | |
|---|---|
| Pulverized camphor | oz. ii |
| Sulphuric ether | dr vi |

Enough oil turpentine to make a six-ounce bottle full Apply the bit stock to the shank A of the shaft, then pour enough of the fluid into the putty cup to cover the lower side of the wheel G.

When the wheel is turned it will immediately enter the glass, boring a very smooth and true hole If a drill press is used, the speed should be slow to avoid throwing the fluid out of the cup or heating the wheel, the last being especially avoided, as all of the constituents of the fluid are very volatile, and it will evaporate quickly if much heat is present

When the hole is nearly through moderate the pressure, but keep on drilling until the wheel has entered the plate H slightly A slight tap with a hammer will now knock the window glass off, and the wheel and shaft may be removed through the hole Do not attempt to remove it through the top unless the hole is very clean, or you will pull the wheel off the arbor

Fig 2 shows how a cracked plate-glass window may be repaired At the ends of each crack and where they intersect a hole is bored to receive a bolt The nut Z of the bolt is made thin, and a rubber washer, made of engine packing is held against the glass by a washer and screw The dimensions given are those used some time ago in repairing a store window The heads of the screws were located inside the store, so as to make it impossible to remove them from the outside. The window is still doing service

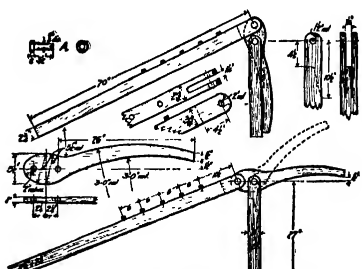
## A WAGON JACK.

BY L. G. BAYLEY

For oiling wagon wheels, or taking them off, some kind of lifting arrangement is resorted to For simplicity of construction and effectiveness the jack herewith described is unique The whole, including the pegs or pins A, is made of oak, the best tough white oak being recommended

The beam is made from 3 by 4 inch timber, planed down to the dimensions given An eye or slot is cut out at the wide end 1 1/16 inches wide by 4½ inches deep This end is rounded off to a radius of 2 inches. Five pegs, 1 inch diameter by 2 inches in length, are driven into the upper side The holes are 1 inch deep and should allow the pegs to have a driving fit

The upright is 27 inches high to the center of the



A WAGON JACK.

fulcrum, made from 3- by 4-inch stuff The end is rounded off to a radius of 1½ inches, and a slotted hole is cut in, as indicated in the detail view

The lever is cut from 1 inch board, 6 inches wide by about 33 or 34 inches in length It should be laid out accurately to the dimensions given in the larger scale view When correctly made and the slot in the upright cut likewise the two holes for the pegs 4 will be in a vertical line, when the lever is pressed down, as shown in the upper general view The pegs A should have a loose fit, and be furnished with small wooden pegs or nails, to keep them in place, when the parts are assembled

To operate the jack the lever is raised as shown in dotted lines in the lower general sketch and the beam slipped in place under the axle of the wagon, which should rest between one of the small pegs in the upper face Bearing on the lever it is pressed down into its lowest position, as shown in the upper sketch, raising the wagon wheel from the ground and securing it in that position indefinitely, without the least chance of its slipping back

Swelling ground cannot be held by timber, means must be provided for relieving the pressure of the ground from time to time. It will cause little trouble if spaces are left between the lagging, through which the pressure may be eased at intervals by removing some of the material Expedients such as packing with straw are valuable only until the swelling becomes sufficient to pack tightly the cushioning substance. When this becomes packed solidly it transmits the pressure to the timbers.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

TIE-CLASP.—A. M. BANTA, New York, N. Y. In this case the invention relates to tie clasps such as are attached to four-in-hand ties to secure them to the shirt front. The object of the improvement is to produce a tie-clasp which can be very simply constructed, readily applied and effective in holding the tie in position.

### Electrical Devices.

SYSTEM OF INSULATION.—J. STEINBERGER, New York, N. Y. Mr. Steinberger's invention relates to systems of insulation for high potential electric conductors to be used in various relations and for various purposes such as power transmission, and for guy wires or cables employed as stays, towers, or for poles, masts, and other supports used in wireless telegraphy, as well as in ordinary commercial work.

CIGAR MOISTENER.—I. C. TEGTMEIER, St. Joseph, Mo. In the present patent the invention has for its object the provision of a device to be used in show cases where the lamp or coil used is connected with a source of electric current which will vaporize a sufficient quantity of water to keep the atmosphere of the case moist so as to prevent the drying out of cigars placed therein.

### Of Interest to Farmers.

PLOW.—J. G. REDMOND, Fairmount, Ill. The intention here is to provide means for lifting the plow cylinder from the ground as when taking the machine to and from the field, this means being preferably constituted by crank arms attached at opposite ends of the plow axle, each having a wheel journaled at its outer end with one of the arms provided with an operating lever and means for positively driving the wheels from the plow.

FRAME FOR MANURE SPREADERS.—F. SCHAAL, New Stapleharst, Neb. The frame is adapted to be attached to a wagon or cart body so as to adapt the same to be used as a manure spreader. The object of the invention is to produce a frame which can be readily attached to the box or body of the cart or wagon and which will be constructed in such a way as to facilitate the removal of the manure from the rear end.

DEVICE FOR DISPENSING TRAVELERS.—J. S. DRAKE, Lancaster, S. C. In spinning cotton the travelers after a few days' use wear out and are replaced. A great amount of time is lost in endeavoring to loosen a single traveler from the entangled mass and the result is a loss to the mill as about four travelers are purchased for one actually used. This invention provides a dispenser which delivers one traveler at a time, which avoids unnecessary waste, and saves considerable time.

### Of General Interest.

CIGAR BUTT FORMER.—J. CARTER, New York, N. Y. The aim in this case is to provide certain improvements in the formation of the butt end of cigars whereby convenient and accurate folding and fixing of the wrapper to the butt end of a cigar is obtained without resort to the expensive manual operation of cutting, shaping and pasting.

DOOR LOCK AND SWITCH.—F. F. SA LMOND, New York, N. Y. The purpose here is to provide for elevators a door lock and switch, arranged to prevent the shaft door from being opened at the time the car is not at the landing, and to prevent the car from being moved away from the landing either in its ascent or descent until the door is again locked.

DISPLAY STAND.—H. ROSENTHAL, Yonkers, N. Y. This stand is intended for use in displaying confectionery, cigars and the like. One object is to provide a transparent protective closure which may be readily applied to a box containing confectionery, cigars and similar articles of merchandise in order to protect the same from moisture, dirt, etc.

INSECT CATCHER.—A. H. LEA, Canby, Ore. In this construction the inventor employs a fruit partially decayed as a bait and utilizes the container of poisonous or destroying liquid as the cover or top for the fruit container. In connection with these containers he preferably employs a light suspended with its lower portion adjacent the surface of the liquid so as to attract the insects at night.

DESK ATTACHMENT.—J. A. SMYLIE and G. D. McELWEE, Centerville, Miss. This device will facilitate the handling of books in office work and consists of a carriage wherein novel features of adjusting and controlling the travel of the same are made use of permitting the carriages to travel in any inclined plane without the use of a track or guard.

MAGAZINE BINDER.—J. POIORALSKI, New York, N. Y. This binder is of book form having a number of leaf retaining bars at the back extending longitudinally and provided with cross-pins, each bar engaging a pin by an endwise movement on the other pin by a lateral movement and castings extending over the opposite end portions of the pins, with the rading of the pin engaged by a lateral movement of the bars movably mounted to pass into and out of overlapping relation to the latter whereby the bars are locked and unlocked.

ROAD-GRADER.—J. P. LYTLE, Buffalo, Mo. The invention is an improvement in road graders or drags and has in view a device of this character in which each scraper takes care of its own dirt from the time it leaves the ditch until it is discharged at the center of the grade, thus avoiding the danger of clogging and making the device easy of operation and light of draft.

### Hardware and Tools.

RIVETING DEVICE.—J. TISCHLER, East Portchester, Conn. The invention pertains to certain improvements in riveting devices and involves a clamp so constructed that it may engage with the head of a rivet to hold the latter in place and at the same time, to leave the opposite end of the rivet exposed so that it may be pounded or beaten into the form of a second head.

UNDERCUTTER SUPPORT.—W. J. WHITWORTH, North Bend, Ore. This invention refers to supports for saws and particularly to the means of adjusting the supporting-arm, and to the means of adjusting the holding dog. Means provide for adjusting the supporting-arm relative to the holding-dog and for adjusting the holding dog relatively to the other parts.

RAKE FOR ROTARY LAWN-CLEANERS.—C. H. MOSHER, Salisbury Mills, N. Y. The invention relates to cleaners such as the one formerly patented to Mr. Mosher. The object is to produce a rake in which the teeth are separately attached, and in which the teeth are arranged in rows or phalanxes, the individuals of each row being advanced progressively with respect to each other.

SEAL LOCK FOR RECEPTACLES.—C. H. JOHNSON, Petaluma, Cal. The invention refers to attachments for signature seals for safety boxes and the like. It also has reference to safety boxes in which a number of persons have separate keys for separate locking openings in the same box and in which a plurality of signature seals are used to cover the locking openings.

DOOR LOCK.—L. F. RUGGERS, Howard, Kan. The object here is to provide a lock of the combination type. It embodies details that adapt the lock for service as a door latch that may be freely operated by means of a knob on the inner side of the door but which will require manipulation of latch controlling disks set to a certain combination for release of the latch bolt from the exterior of the door.

NUT LOCK.—C. F. DAVIDSON and H. J. MADDOX, Ozona, Texas. The invention is an improvement in nut locks and has for an object to provide a construction affording a pawl-like device carried in the body of the nut and adapted to bed itself in the bolt threads or seat in grooves or channels formed therein.

RATCHET WRENCH.—W. COOK, Phillipsburg, N. J. This wrench has a ratchet wheel presenting a socket which may be applied to the head of a nut or bolt for rotating the same. This wheel is mounted in a ratchet head and is adapted to be advanced by means of a lever operating through a pawl. The socket is constructed in such a way as to enable it to retain inset jaws which reduce the size of the socket or enable it to be used as a pipe wrench.

### Heating and Lighting.

INVERTED INCANDESCENT GAS LAMP.—H. HAAF, 30a Blumenstrasse, Berlin, Germany. This invention has for its object an incandescent gas burner in which by making the metal walls of the burner head and of the mixing tube of appropriate thickness and if desired in combination with means for conducting away the heat, a regulation of the heating effect is obtained.

### Household Utilities.

AUXILIARY WATER-CLOSET SEAT.—J. H. STEFFER, New York, N. Y. This invention provides an auxiliary seat for the use of small children in connection with the regular seat of a water-closet, privy, hospital commode or other night soil receptacle, the auxiliary seat being so designed that it affords the maximum convenience and comfort and so that it can be placed upon the regular seat board used by adults and firmly maintained in position.

CURTAIN POLE BRACKET.—H. LUTTICH, New York, N. Y. In the present patent the invention has reference to brackets such as used for supporting curtain-poles. The object of the inventor is to produce a bracket of simple construction which can be readily attached to a window casement and which will afford support for a curtain pole.

MATCH RECEPTACLE.—H. WARK, New York, N. Y. The object in this instance is to provide a match receptacle to be employed with safety matches or with ordinary matches, from which the matches can be taken one at a time without difficulty, which can be easily and expeditiously filled with matches, and which is neat and attractive in appearance.

SHUTTER AND VENTILATOR.—W. P. RYLANDER, San Marcos, Texas. In this instance the invention pertains to improvements in shutters of the slatted type and has for its object to provide a shutter which may be used for ventilation alone, for ventilation and at the same time securing privacy, and finally to produce a shutter which may be so adjusted as to be practically a solid blind.

TEA AND COFFEE SAVER.—E. F. CONSETT, New York, N. Y. The more particular purpose in this patent is to provide a cage movably mounted within a pot and adapted to be raised and lowered in order to expose the tea, or coffee to the liquid. Means provide for holding the cage in a plurality of different positions, so that the cage and its contents may be in one instance completely submerged and in another completely raised out of the liquid.

### Machines and Mechanical Devices.

LIFTING JACK.—G. R. BOOTH, Chana, Ill. The improvement has reference to lifting jacks, and has for its object to provide one with all the parts so proportioned and disposed that it is compact, strong while of light construction, easy to operate and the parts of which, when at rest, will rattle very little, if at all.

VENDING MACHINE.—W. ASBURY, New York, N. Y. An object here is to provide a machine with mechanism by the means of which a practical two-coin machine is produced. Another object is to provide means by which a coin will bring a lever into operative position to be actuated by an arm secured to a shaft by the means of which the ejecting mechanism may be actuated.

APPARATUS FOR THE PURIFICATION OF WATER.—J. P. LADOR, Taverny, Avenue De Lariviêre, Seine, France. The invention relates to mechanism for purifying water used for various purposes, and especially for manufacturing, the more particular purpose being to rid water of calcareous matter and various salts which might otherwise coat the interior of boilers. A few moments of each week of an operator's time is sufficient to keep the apparatus in constant operation.

MULTIPLE SELF-INKING STAMP HOLDER.—V. W. HOLMES, Fort Thomas, Ky. More particularly the invention relates to improvements whereby any one of a series of stamps carried by the holder may be brought into operative position in respect to the inking device and, at the same time be in proper position for application to the surface to be stamped.

SHAPER ATTACHMENT.—I. KRAMER and C. BROWN, Evansville, Ind. By means of the attachment material may be turned into various shapes by adjustment of different forms to the machine, the forms being secured to the shaft in which the material is secured for rotation, and the forms acting on the knives to produce the desired result. Means permit the gradual movement of the material to be treated, against the knives and to hold it yieldingly in this direction.

PAPER FOLDING MACHINE.—A. B. COLSON, L. F. McCLINTOCK, W. C. STEWART and H. H. McCARTNEY, Marion, Ill. The machine is particularly designed to prepare by folding or doubling the tie sack and pouch labels used by postal and post office clerks. The machine will fold the slips and print the name and date thereon, and deliver the folded labels in order to a receiving box. A novel feeding mechanism is also provided for automatic action.

UNIVERSAL CONTROLLING VALVE.—W. I. ASH, F. F. HILDRETH and F. N. HUMBLEY, Terre Haute, Ind. This invention relates to valves for controlling the operations of mechanism which are actuated by compressed air, steam or vapors under pressure. An object is to provide a device in which by the simple manipulation of an operating handle the control of the various pipes and cylinders in an air brake system is effective.

STENCIL MACHINE.—R. C. WRIGHT, Richmond, Va. This invention is more particularly designed for use in places where a number of packages or articles have to be impressed with the same name and address, although it may be conveniently used when only one name and address is to be impressed. The main object is to provide a device in which a name can be quickly set up and then impressed upon the article at one operation.

BELT RACK.—R. L. SMITH, Lincoln, Neb. The rack occupies little room and carries many belts which may be readily moved to the desired position to permit of their being unrolled. Another object is to so construct the device that the belting will be prevented from slipping from the spindles by the frame of the device, it being possible to move the spindles to a position at which the belts can be readily moved.

MIXING MACHINE FOR FERTILIZERS OR CEMENTS.—C. R. HERMICA, Atlanta, Ga. The machine comprises a crusher which is employed in connection with one of the hoppers, which enables one of the ingredients to be crushed as the mixing takes place. The construction involves a tumbling barrel which receives the ingredients to be mixed and this barrel is rotated continuously in an inclined position so as to bring about a thorough mixture of the different ingredients.

BRAKE FOR ELEVATORS.—W. R. ELLIOTT, Somerset, Ky. Means are here provided whereby the action of the car can be controlled in the ordinary operation, means whereby the car may be automatically arrested in the event of its starting to fall, means whereby a car may be held immovably in any arrested position, and to simplify the construction and arrangement of the parts constituting the brake, and to decrease the cost of the device.

BELT FASTENER.—C. O. L. CARDELL, Pearl River, N. Y. The object here is to provide a fastener for securely connecting the ends of the belt with each other so that the belt is exceedingly flexible at the joint, is not liable to fray or ravel at the junction or at the sides of the joint, and the belt is guided to run centrally on the crowns of the belt pulleys over which the belt passes.

CIGAR-CUTTING MATCH RECEPTACLE.—J. P. CROSTHWAIT, Sadieville, Ky. In this device the matches are delivered successively and in a lighted condition, it delivers a match and simultaneously cuts the end of a cigar, it stows the matches in a receptacle to be delivered therefrom successively, and it maintains the lock in the receptacle in operative position until the matches are completely or nearly exhausted.

AUTOMATIC REGULATING DEVICE FOR WATER TANKS.—W. L. BAUGHMAN, Harrisburg, Pa. The device is particularly applicable for keeping filled the tanks or troughs disposed in the center of a railway track for the purpose of supplying water to a passing engine. The device is actuated by a float in which the valve mechanism is operated directly by the water pressure from the water main.

### Prime Movers and Their Accessories.

GOVERNOR.—J. P. NICKOLOW, Evansville, Ind. Particularly stated, this invention relates to improving the valve mechanism forming a part of the turbine and also improving the form of the weights operated by centrifugal force, and also improving the form of parts associated with these weights and with the valve controllable by the governor.

### Railways and Their Accessories.

FLUE POINT AND ITS ATTACHMENT TO FLUE-SHEETS.—C. S. COLEMAN, Spokane, Wash. Mr. Coleman has demonstrated by numerous experiments, that, by providing the flue point with a recessed shoulder, and by employing a gasket of soft metal, the same being provided with a bead interposed between the flue-sheet and the shoulder of the flue-point, and by expanding and beading the outer ends of the flue-point he is able to form a tight joint which practically avoids leakage.

### Pertaining to Recreation.

GAME APPARATUS.—W. F. SCHNEIDER, Cincinnati, Ohio. In this patent the invention relates to games and it has for its object the provision of a board and moving pieces which may be constructed at little expense and which may be used to play an interesting and novel game. The game comprises a base ball field, bases, runners, scoring of points, the playing of innings, and other features of base ball.

SOUNDING TOY.—A. H. F. SCHLIECKMAN, Vinita, Okla. The toy is adapted to produce snapping sounds of various tones and qualities. The object of the invention is to produce a device which may be cheaply manufactured and which is adapted to produce sounds of various pitches by varying the manner of manipulating the same.

AMUSEMENT DEVICE.—R. FARRELL, Tappan, British Columbia, Canada. Among the principal objects which the present invention has in view are: To provide an apparatus whereby is produced the illusion of floating in mid-air, and to produce a simplified construction for an apparatus designed to produce the above-mentioned desired effect.

### Pertaining to Vehicles.

BICYCLE AND MOTOR CYCLE HOLDER.—W. A. SETTLE, Wallace, Idaho. The device is permanently carried on the frame of the cycle, and can be adjusted to hold the cycle in an upright position when not being ridden, the support being adjustable to engage one of the pedals of the cycle so that the latter will be firmly held against movement should the cycle be in a standing position on a grade.

LOCKING DEVICE.—F. D. WINTRINGHAM, New York, N. Y. The invention relates to manually controlled levers such as the controlling levers of automobiles and the like, and its object is to provide a device arranged to securely hold the controlling lever in position against accidental displacement, and to prevent the operator from shifting the controlling lever too far.

### Designs.

DESIGN FOR A COVERED DISH OR SIMILAR ARTICLE.—C. ZIEGLER, Limoges, France. The design presented is an interesting and ornamental covered oblong dish, with a sloping top and base and end handles. The design includes the representation of neat yet fanciful scroll work, forming a pleasing ornamentation.

DESIGN FOR A GLASS GOBLET OR SIMILAR ARTICLE.—C. O. NORTHWOOD, White Mills, Pa. The ornamental design in this case represents a glass goblet of exquisite body curves, a slightly tapering narrow column connecting it with a flat base. The ornamental features cut in the goblet are very artistic. Mr. Northwood has designed another glass goblet of the same general curves and shape, but with flower ornamentation very dissimilar, and also a third glass goblet with a somewhat decided departure from the other two, and with a broader flower ornamental display in the body.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## NEW BOOKS, ETC.

**The History of French Literature from the Oath of Strasbourg to Chanticler.** By Annie Lemp Konta. New York and London: D Appleton & Co., 1910. 8vo., 850 pp. Price, $2 50.

As a general rule, an author divides the prospective readers of his work into two categories, and a book is usually designed with these divisions in view It is intended for the perusal either of the student, or of the general, casual reader, and seldom answers the purposes of both. Mrs. Konta, however, has furnished us with an exception to this generalization, in her excellent history of French literature, and it can truthfully be said that both the student and the lay reader will find much of interest and of high literary value in her book The work is a concise, and clear chronology of practically the whole of French literature, beginning with the formative period The history is technically most thorough and systematic, and that it is the result of long continued, conscientious study and investigation becomes apparent to even the most cursory reader It is naturally difficult to treat a subject of such comprehensive nature, so that its necessary brevity does no violence to the mass of information which must be included but the author appears to have solved this problem successfully The appended bibliography is excellent Another good feature is found in the thorough index, an element so necessary in a book of this kind and so seldom properly done Aside from any pedagogical value, the book is of great interest owing to the many interesting and amusing anecdotes and stories, which the author has compiled from different sources, regarding most of the prominent figures of French literature Many of the anecdotes have been discovered in obscure French sources, and appear for the first time in English in Mrs Konta's book.

**The History of Astronomy** By George Forbes M A, F R S, M I C E New York and London G P Putnam's Sons, 1909 16mo, 200 pp

Prof Forbes has written a very instructive little book on the history of astronomy which he divides into four periods—the geometrical dynamical, observational and the physical Thus he traces the evolution of intelligent thought in the progress of astronomical discovery and by recognising the different points of view of the different ages gives credit even to the ancients Although the history has been necessarily curtailed, still it lays before the reader in a limited space just enough about each age to illustrate its tone and spirit to give some conception of the ideals of the works to present logically and gradually different and new points of view and additional means of investigation

# Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th or will be sent by mail on request.

(12203) B S writes: I here add my experience with treating old dry batteries with hydrochloric acid as it once said in your paper, and this is my view of the matter: If a person is in a place where batteries are hard to get, or if he only cares for a set of batteries that will finish the season, etc., or if he thinks the time that he spends on fixing the old batteries is cheaper than a new set, fixing the old batteries is all right. I am in a place where batteries are hard to get and are high. I have lots of time to spend on such jobs; the acid cost me fifty cents. I don't count my time. I find the batteries will do about a third or half of the work a new set will do. A. We think this is reliable.

(12204) F McC asks: Does a train while running on an absolutely level track and at a very high rate of speed have any less pressure on the rails than when at rest? We have it figured out by a learned professor that a train running around the entire surface of the earth at the rate of 491 miles per hour would have no pressure on the rails, but we think that he has taken into consideration the circular shape of the earth's surface, and figures that the centrifugal force would throw it away from the center and cause it to have no pressure on the rails at the speed. What we want to know is that if it were possible to build a track of equal length, absolutely level, regardless of the earth's surface, as level as the lines of a ray of light, would a train running at a high speed have any less pressure on the rails than when at rest? If it does have less pressure, what law causes it to have less pressure? What force causes it to rise? A. There is no reason whatever why a train running at any rate of speed should reduce its pressure upon the rails if the earth's surface is considered as a plane and centrifugal force is neglected while gravity remains constant, unless, of course, it is equipped with aeroplanes at such an angle of attack as to use wind pressure to decrease its rail pressure. It is easy to calculate the speed at which centrifugal force will theoretically balance the attraction of gravity, but it is demonstrably untrue that there is any such effect in practice, for a combination of reasons too long to be discussed here. It may be shown that the driving wheels of a locomotive press less on the rail for a part of their revolution at high speeds, and even leave it altogether, but this is entirely due to inadequate balance of the thrust of the reciprocating parts at such speed, and has no connection with the principle of your problem. It is imaginable also that a train might ascend a gradient on a trestle, for instance, at such a speed as to leap off at the end and be carried some distance by the ballistic effect of its momentum, from which it might be argued that reduction of rail pressure by speed is analogous, but this again is outside the limits laid down in your question.

(12205) H L F asks: I would like to know if a head of three or four feet of water with an abundant supply of the same can be used in a turbine with anything like a fair efficiency in operation. Can you give me an idea of what one could expect to achieve in the efficiency of a turbine so placed? A. There is no reason whatever why an unlimited supply of water with only four feet of head should not generate a large amount of power with economy and efficiency, provided a suitable turbine, especially designed for low head, is used, and there are many good ones. The theoretical horse power developed would be 0.00758 Q, in which Q is the quantity of water in cubic feet per minute available, of which at least 75 per cent should be obtainable in actual useful work with a suitable turbine.

A kindly critic who has been a professor of mathematics for many years has objected to the answer to an inquiry regarding the equation of time which we printed few weeks since, that it is not sufficiently exact. From the point of view of a mathematician or the astronomer the criticism has some reason. The degree of inexactness of our answer may be seen from the fact that the difference from day to day for the years 1909 and 1910 is not as much as 9 seconds at any time excepting for a few days near the end of December, and is less than 5 seconds except for a short time near the autumnal equinox. Anyone needing the equation of time exactly must go to the Astronomical Ephemeris for it, where it is given for each day of the year at Greenwich apparent noon, with the difference for one hour from this time for any other longitude can be calculated. For all common uses, such as setting a clock for local time by the noon mark or the rising of the sun as we used to do when we were a farmer boy in the country, the equation of time as given in an almanac is all that is necessary.

## TWO REMARKABLE SHOWS.

(Continued from page 196.)

The W. H. Mullins Company exhibited, as heretofore, several of its small steel boats, but the construction novelty of the show was a hull built of phosphor-bronze plates riveted together and attached to the ribs by means of U-shaped clamps passing over the latter and riveted to the hull. These boats were constructed by the Davit & De Groot Company, a firm which has had a great deal of experience building riveted steel-hull lifeboats for the United States government. The phosphor-bronze hull has a great advantage over the steel hull on account of its non-corrosive qualities, and in addition to this the new construction does away with rivets through the ribs. In a 36-foot cruiser exhibited by the same concern, there was installed a new type of hydraulic steering gear, which consists of two curved cylinders with movable plungers placed at the steering wheel and connected by means of small copper tubing to similar cylinders placed at the rudder The cylinders and tubing are filled with a mixture of oil and glycerine, a very slight movement of the transmitting pistons at the steering wheel being sufficient to actuate the rudder positively The mixture used is non freezing, so that cold weather does not affect it This steering gear appears to be a decided improvement over the usual form, since it is easily worked and is more or less self locking

Probably the most popular craft exhibited were the open speed boats, which vary in price from $1,000 to $3,000 or $4,000 Twenty five miles per hour was the highest speed guaranteed by any of the makers of these boats exhibited, and the majority of them do not make more than 18 or 20 miles an hour For the man of small means who is content to travel slowly, there were boats (open launches) varying in price from $104 to $1,000 Some of these launches were fitted with automobile tops The cruisers were larger and more comfortably fitted out than ever before. The price of these boats is low compared with their size and usefulness. An average speed of 10 or 12 miles an hour is all that is aimed at with this type of boat. In many instances electric lights run from an ignition dynamo were fitted, while comfortable bunks, a small galley, etc., were the rule

The exhibit of engines this year was a large one While many manufacturers still stick to the 2-cycle motor, this is used chiefly on low powered, slow-speed boats having one or two-cylinder motors The speed craft almost invariably are fitted with 4 or 6-cylinder motors of the 4 cycle type A 100 horse-power Mietz & Weiss reversible kerosene-oil engine was one of the striking engines exhibited, also a 225-horse-power 8-cylinder 4-cycle motor built for a racer by the Jencick Motor Company The Dean Manufacturing Company showed the 8-cylinder 80-horse-power 2-cycle engine with which they made their record run from St. Louis to New Orleans last year in the "Brer Fox II" The Standard Motor Construction Company exhibited a complete line of motors, including the 125-horse-power double-acting 6-cylinder engine used by the Russian government on its submarine The smallest and lightest marine motor exhibited was the Waterman 12-horse-power 4-cylinder motor shown in a small 14-foot boat intended for a young lady This motor weighed about 100 pounds complete. One of the novelties of the show was an inclosed fly wheel having pockets around its periphery. The discharge of the exhaust into these pockets helped to turn the motor, the flywheel thus acting as a muffler. A new form of timer, consisting of a small cogwheel revolving within an internal gear, was exhibited. A specially built motor boat fitted with 150 compartments, and intended to be used in navigating the rapids at Niagara was shown by the Detroit Boat Company. With this

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES

WE ARE WELL EQUIPPED to manuf. some patented article, electrical and woodworking, on royalty or other satisfactory basis. Will entertain exploiting. Electrical, Box 773, N. Y.

Inquiry No. 8918. For manufacturers of "Wydl's Electro Catalytic Sparking Plug."

WANTED TO BUY, a gasoline locomotive, suitable for hauling thirty or forty tons on a three per cent. grade. For information address Gardner H. Narbonne, 1120 Juliet Street, Los Angeles, Cal.

Inquiry No. 8997.—Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power meters.

TO GET ACQUAINTED I will place your 25-word advertisement in twenty-five leading newspapers for $10. For particulars address J. L. Causey, 810 Fourteenth Street, Norfolk, Va.

Inquiry No. 9011.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

## PATENTS FOR SALE

SENSATIONAL RIDING amusement device patent. Sure winner. Write for descriptive illustration. Sell reasonable. J. W. Bourke, 17 Leyland St., Dorchester, Mass.

Inquiry No. 9016.—Wanted machinery necessary for an installation of a plant for reducing salt by a modification of the Bessemer process.

FOR SALE.—U. S. patent rights to highest bonafide bidder, April 2, 1910, telephone muffler. Telephone booths no longer necessary. See descriptive notice in February 26th issue. W. D. Pisuab, 303 Lexington Ave., N. Y.

Inquiry No. 9013. Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

## HELP WANTED.

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres. The Nat'l Co-op. Real Estate Co., Suite 376, Marden Building, Washington, D. C.

Inquiry No. 9029. Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

## FOR SALE

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads, 2 to 40 in. Price only $42.50. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9034.—Wanted, the address of the manufacturers of "Cyein Ball Bearing Suspenders."

FOR SALE. Hand power wood sawing machine. You can cut twenty-one rick a day. United States Patent 935,151; Canada, 118,033. Address T. Kimura, 1313 C Street, Tacoma, Wash.

Inquiry No. 9038.—Wanted the address of the Chipman Electric Purifying Co.

## MISCELLANEOUS.

WANTED names of firms manufacturing celluloid polishing wheels and machines or information regarding same. Address B.-B., Box 773, N. Y.

Inquiry No. 9049. Wanted the address of Farney Safety Razor Co.

## LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9052.—Wanted, address of firms who install plants to manufacture nitrogen.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9055. Wanted address of parties interested in Log Cleaning Machines.

Inquiry No. 9057. For manufacturers of glass and china balls, used as fixtures or ornaments on lightning rod equipment, also weather vanes for same purpose.

Inquiry No. 9060. Wanted to buy machinery to manufacture seed corn racks.

Inquiry No. 9062.—Wanted complete outfit for export for making rice-flakes and wheat flakes.

Inquiry No. 9064. Wanted to buy machinery for manufacturing chewing gum, such as rolling, cutting or wrapping machinery.

Inquiry No. 9069.—For the address of firms making chain cloth, something like ladies' purses are made of.

Inquiry No. 9070.—Wanted, manufacturers of metal castings for art lamp shades.

Inquiry No. 9071.—Wanted, the address of parties making moulds for large concrete vases for flower pots.

Inquiry No. 9072. Wanted, machinery for making fine chains, such as used by jewelers, etc.

Inquiry No. 9073.—Wanted, machinery to manufacture cocoanut oil; also the crude material.

Inquiry No. 9074. Wanted to buy old model locomotives or steamboats such as were exhibited with nickel-in-the-slot attachments in ferry-houses, etc.

Inquiry No. 9075. Wanted to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

Inquiry No. 9076.—Wanted the address of parties in Canada who could make a safety razor.

Inquiry No. 9077. Wanted the address of manufacturers that make small articles of wood, such as checker boards, etc.

Inquiry No. 9078. Wanted, the address of manufacturers of sewer pipe made of fiber and asphaltum, suitable for laboratory use.

Inquiry No. 9079.—Wanted, parties to make a special steel plate rolled for "angle bars" in large quantities.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste-making machinery.

Inquiry No. 9081.—Wanted, manufacturers of a mixing machine to mix powdered and fluid ingredients to a thin dough; also molds to put such dough in to dry, the size to be about 4¼ inches long, 3¼ inches wide and 1¼ inches high, making the form of a cake like sapolio.

Inquiry No. 9082.—Wanted, the address of manufacturers of the bead fringe used on art shades for electric lamps, etc.

Inquiry No. 9083.—Wanted, the address of firms manufacturing small beer brewing plants, from 25 to 100 gallons a day.

Inquiry No. 9084.—Wanted, the address of manufacturers of Irwin portable bath tubs.

Inquiry No. 9085. Wanted, to buy longitudinal hollow perforated tubing.

Inquiry No. 9086.—Wanted, to buy a pine wood pealer.

Inquiry No. 9087.—Wanted a machine for hard swing back saw blades; also a machine for setting same when they have been toothed.

Inquiry No. 9088.—Wanted, the address of manufacturers of family sized peanut pulverizers for making peanut butter.

Inquiry No. 9089. Wanted, the address of manufacturers of galvanized steel perforated hollow tubing.

Inquiry No. 9090.—Wanted manufacturers of suspender and supporters supplies, also patent adjustable bachelor buttons.

Inquiry No. 9091.—Wanted, parties to manufacture a new patented clothes hanger.

Inquiry No. 9092. Wanted, the address of some firm who manufacture permanent lamp wicks.

Inquiry No. 9093.—Wanted, manufacturers of metal specialties and novelties.

# Home-Made Experimental Apparatus

In addition to the following articles, the Scientific American Supplement has published innumerable papers of immense practical value, of which over 17,000 are listed in a carefully prepared catalogue, which will be sent free of charge to any address. Copies of the Scientific American Supplement cost 10 cents each.

If there is any scientific, mechanical, or engineering subject on which special information is desired, some papers will be found in this catalogue, in which it is fully discussed by competent authority.

A few of the many valuable articles on the making of experimental apparatus at home are given in the following list:

ELECTRIC LIGHTING FOR AMATEURS. The article tells how a small and simple experimental installation can be set up at home. Scientific American Supplement 1551.

AN ELECTRIC CHIME AND HOW IT MAY BE CONSTRUCTED AT HOME is described in Scientific American Supplement 1566.

THE CONSTRUCTION OF AN ELECTRIC THERMOSTAT is explained in Scientific American Supplement 1566.

HOW TO MAKE A 100-MILE WIRELESS TELEGRAPH OUTFIT is told by A. Frederick Collins in Scientific American Supplement 1605.

A SIMPLE TRANSFORMER FOR AMATEUR'S USE is so plainly described in Scientific American Supplement 1572 that anyone can make it.

A ½ H.P. ALTERNATING CURRENT DYNAMO. Scientific American Supplement 1558.

THE CONSTRUCTION OF A SIMPLE PHOTOGRAPHIC AND MICRO-PHOTOGRAPHIC APPARATUS is simply explained in Scientific American Supplement 1574.

A SIMPLE CAMERA-SHUTTER MADE OUT OF A PASTEBOARD BOX, PINS AND A RUBBER BAND is the subject of an article in Scientific American Supplement 1578.

HOW TO MAKE AN AEROPLANE OR GLIDING MACHINE is explained in Scientific American Supplement 1582, with working drawings.

EXPERIMENTS WITH A LAMP CHIMNEY. In this article it is shown how a lamp chimney may serve to indicate the pressure in the interior of a liquid, to explain the meaning of capillary elevation and depression, to serve as a hydraulic tourniquet, an aspirator, and intermittent siphon, to demonstrate the ascent of liquids in exhaustive tubes, to illustrate the phenomena of the bursting bladder and of the expansive force of gases. Scientific American Supplement 1583.

HOW A TANGENT GALVANOMETER CAN BE USED FOR MAKING ELECTRICAL MEASUREMENTS is described in Scientific American Supplement 1584.

THE CONSTRUCTION OF AN INDEPENDENT INTERRUPTER. Clear diagrams giving actual dimensions are published. Scientific American Supplement 1615.

AN EASILY MADE HIGH FREQUENCY APPARATUS WHICH CAN BE USED TO OBTAIN EITHER D'ARSONVAL OR OUDIN CURRENTS is described in Scientific American Supplement 1618. A plunge battery of six cells, a two-inch spark induction coil, a pair of one-pint Leyden jars, and an inductance coil, and all the apparatus required, most of which can be made at home.

SIMPLE WIRELESS TELEGRAPH SYSTEMS are described in Scientific American Supplements 1363 and 1381.

THE LOCATION AND ERECTION OF A 100-MILE WIRELESS TELEGRAPH STATION is clearly explained with the help of diagrams, in Scientific American Supplement 1622.

THE INSTALLATION AND ADJUSTMENT OF A 100-MILE WIRELESS TELEGRAPH OUTFIT. Illustrated with diagrams. Scientific American Supplement 1623.

THE MAKING AND THE USING OF A WIRELESS TELEGRAPH TUNING DEVICE. Illustrated with diagrams. Scientific American Supplement 1694.

HOW TO MAKE A MAGIC LANTERN. Scientific American Supplement 1546.

THE CONSTRUCTION OF AN EDDY KITE. Scientific American Supplement 1555.

THE DEMAGNETIZATION OF A WATCH is thoroughly described in Scientific American Supplement 1561.

HOW A CALORIC OR HOT AIR ENGINE CAN BE MADE AT HOME is well explained, with the help of illustrations, in Scientific American Supplement 1573.

THE MAKING OF A RHEOSTAT is outlined in Scientific American Supplement 1594.

Good articles on SMALL WATER MOTORS are contained in Scientific American Supplements 1494, 1049, and 1406.

HOW AN ELECTRIC OVEN CAN BE MADE is explained in Scientific American Supplement 1472.

THE BUILDING OF A STORAGE BATTERY is described in Scientific American Supplement 1433.

A SEWING-MACHINE MOTOR OF SIMPLE DESIGN is described in Scientific American Supplement 1210.

A WHEATSTONE BRIDGE. Scientific American Supplement 1595.

Good articles on INDUCTION COILS are contained in Scientific American Supplements 1514, 1522, and 1527. Full details are given so that the coils can readily be made by anyone.

HOW TO MAKE A TELEPHONE is described in Scientific American Supplement 966.

A MODEL STEAM ENGINE is thoroughly described in Scientific American Supplement, 1527.

HOW TO MAKE A THERMOSTAT is explained in Scientific American Supplements 1561, 1566, and 1566.

ANEROID BAROMETERS. Scientific American Supplements 1500 and 1554.

A WATER BATH. Scientific American Supplement 1464.

A CHEAP LATHE UPON WHICH MUCH VALUABLE WORK CAN BE DONE forms the subject of an article contained in Scientific American Supplement 1562.

Each number of the Scientific American Supplement costs 10 cents by mail.

Order from your newsdealer or from

MUNN & CO., Inc., 361 Broadway, New York

(Concluded from page 209.)

boat, two men expect to make the hazardous 7-mile trip through the rapids and the whirlpool next summer to Lewiston, Canada.

The motor boat industry, as mirrored by the 1910 show, is increasing by leaps and bounds. Already there are 50,000 motor boats in use in this country, and it is safe to say that by the end of another year this figure will be materially increased.

### THE FIRST AMERICAN AERONAUTIC SHOW AT BOSTON

The two general views of the Boston aeronautic show reproduced herewith will give our readers a good idea of how well-filled was the large hall at Mechanics Building with the machines of American inventors at the recent show. While a few of the aeroplanes exhibited were on the lines of some of the successful European models, most of them were patterned after American models, such as the Curtiss and Wright biplanes and the Pfitzner monoplane. In one of our illustrations a monoplane on the general lines of the Bleriot (the "Morok") with the sliding wing tips invented by Pfitzner instead of wing warping, appears in the foreground, while the large Antoinette type with triangular body and the smaller Bleriot type monoplane were both exhibited by the Scientific Aeroplane and Airship Company of New York. Both of these machines were constructed by Stanley Y. Beach.

Another general view of the hall shows the former of these two monoplanes in the foreground. Another monoplane of original construction (the "Burlingame") appears in the distance, while hanging from the ceiling is a biplane glider constructed and used by the students at Boston "Tech," and just below this another glider built by two boys after a description published in the SCIENTIFIC AMERICAN. The balloon "Boston" the club balloon of the Aero Club of N. E., is seen partially inflated in the center of the hall, while on the right-hand side are seen several balloon baskets, among them being that of Leo Stevens's small one-man balloon "Mercury" and the basket of a 160,000-cubic foot balloon capable of carrying 20 passengers.

The L. A. W. biplane and revolving cylinder 2-cycle motor was one of the novelties of the show. This biplane was constructed somewhat on monoplane lines, there being a rectangular body extending out behind and carrying the biplane horizontal rudder for steering up and down. The motor was mounted on trunnions close in front of the main planes, which mounting makes it possible to direct the propeller upward slightly when the machine is running along the ground in order to rise. The new revolving-cylinder motor used on this machine is said to be one of the lightest motors of this type yet produced. It is soon to be put on the market in two sizes of 50 and 100 horsepower.

Besides the aeroplanes shown in our photographs, there were numerous other full-size machines. Most of these were described in our last issue. A Farman machine like that used by Farman at Brighton Beach in 1908 was put on exhibition when the show was half over. This machine was the only aeroplane said to have made a short flight previous to the opening of the show.

### THE UNBALANCED BULLET.

(Continued from page 203.)

based, indicated plainly that the cause, so simple after discovery, was not even surmised. Their attempts to reduce it were based upon the theory that the blast of powder gases at the muzzle, or some condition of the rifle bore at the muzzle, was responsible for this apparent sudden change in direction of the bullet's flight at this place.

Persistent screen shooting and continued elimination of errors that were

(Concluded on page 211.)

(*Concluded from page 210.*)

known, indicated clearly that this X error was not the only error. Another cause was at work which added to or subtracted from the X error, and while experimenting for this the author designated it the "Y error."

He had known for years that tipping bullets make a spiral flight as they pass through the air. E. A. Leopold determined the diameter of some of these spirals several years ago. It was generally believed that a bullet often makes a spiral flight over the range, and the cause of this Y error at the target seemed to have some connection with this spiral in the air, which nearly all unbalanced bullets describe. The author's own screen shooting exhibited clearly the diameter of many of these spirals and the distance from the muzzle at which the spirals commenced. He found the cause of the Y error to be as simple as the cause of the X error.

The X error spiral ends at the muzzle, while the Y error, in the air, commences about 12 feet from the muzzle. The bullet makes an apparent change in its direction when it leaves its X spiral at the muzzle, and it makes another change in its direction when it goes into its Y spiral. The resistance of the air upon a tipping bullet produces its air spiral, and the rigid walls of the rifle barrel produce the X spiral described by an unbalanced bullet in the bore. The pitch of the X spiral, or the distance of one turn of the spiral to the next, is the same as the rifle twist, which for a 0.32 caliber is about 12 inches. The pitch of the Y or air spiral is about 45 feet.

The diameter of the bore spiral varies from a fraction of a thousandth of an inch to several thousandths of an inch. The diameter of the air spiral varies from a few thousandths of an inch to 7/16 of an inch, depending upon the amount the bullet tips in its flight. The air spiral, of course, results from the fact that the tipping bullet does not point in the direction of its flight.

The causes of these two errors, X and Y, are the same in principle, but their positions are reversed. The workings and explanations by actual experiments, well illustrated, are set forth very elaborately by the author.

The following conclusions may be drawn from the book:

In careful rest target work, under favorable shooting conditions, the X + Y error at the 100 or 200-yard target is about 80 per cent of all errors. The X and Y results from the fact that the tangent of a spiral (c c) forms an angle with the axis of its spiral (d d), as may be seen in Fig. 3. The bullet as a whole makes a spiral flight while in the rifle, because it is unbalanced or because it does not lie central and straight with the bore. It makes a spiral in the air because it is a tipping bullet. It is a tipping bullet because it was unbalanced when it left the muzzle. The unbalanced bullet, with respect to the center of the rifle bore, is therefore the prime cause of its X and Y errors.

To overcome the error which is inherent in the rifle and its ammunition, the bullet, before being shot, must be a balanced one, that is, its center of gravity must coincide with its center of form. The powder charge must produce uniform pressure from shot to shot. The rifle barrel and ammunition must be so constructed that the projectile remains balanced throughout the entire bore.

To have a projectile start from the muzzle in the right direction, that is, in the line which forms the center of the bore, the entire bullet just as it leaves the muzzle must be symmetrically balanced around the line of fire. Any reasonable rifleman would admit this last statement. What the author's work has disclosed, however, is to point out clearly the fact and its importance, and to show mathematically that practically the whole error at target attributable to the modern rifle and its ammunition originates in the unbalanced projectile.
